Discussion Questions

[Discussion instructions: For each discussion question, prepare approximately 500 spoken words for delivery over 2.5–3 minutes (approximately 167–200 words per minute). Address the ten subject prompts below in their stated order. Use the opening to frame the issue and the closing to synthesise the principal findings, conclusions and unresolved questions.]

Copyright 2026, James M. Atkinson

V011-C14-DISCUSSION-001. A certificate covers the receiver but not the selected gain state. How should a reviewer respond?

- 01. Moderator, opening proposition: Introduce the exact dispute, “A certificate covers the receiver but not the selected gain state. How should a reviewer respond?” Put this particular dispute to the panel: A certificate covers the receiver but not the selected gain state. How should a reviewer respond. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §14.18 Close the calibration record across the working interval (p. 8147)

- 02. Student A, terminology and scope: Agree the operational meanings of certificate, covers, receiver and gain, reviewer, respond in “A certificate covers the receiver but not the selected gain state. How should a reviewer respond”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §14.18 Close the calibration record across the working interval (p. 8147)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of A certificate covers the receiver but not the selected gain state; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §14.8 Calibrate noise without confusing it with detection (p. 8116)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Calibrate noise without confusing it with detection”. Do not hide the gap under an arbitrary uncertainty allowance or infer coverage from serial identity Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §14.8 Calibrate noise without confusing it with detection (p. 8116)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A certificate covers the receiver but not the selected gain state; explain what each record can establish State what the existing record establishes, what it does

Copyright 2026, James M. Atkinson

not establish, and which further measurement would change your opinion. Source: §14.2 Attach calibration to a stated measurement result (p. 8105)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “Calibrate noise without confusing it with detection”. Do not hide the gap under an arbitrary uncertainty allowance or infer coverage from serial identity Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §14.8 Calibrate noise without confusing it with detection (p. 8116)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. Identify the omitted scope, request targeted characterization or narrow the claim, and retain the valid covered calibration Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate between them without changing the measurand. Source: §14.18 Close the calibration record across the working interval (p. 8147)

- 08. Student D, answer to Student E: Design a discriminating experiment involving A certificate covers the receiver but not the

Copyright 2026, James M. Atkinson

selected gain state: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §14.18 Close the calibration record across the working interval (p. 8147)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A certificate covers the receiver but not the selected gain state; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §14.2 Attach calibration to a stated measurement result (p. 8105)

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving A certificate covers the receiver but not the selected gain state: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Present a repeatable, authorised test with the receiver settings, controlled variable, expected responses and a rejection criterion. Ask Student H to identify an alternative that could survive

Copyright 2026, James M. Atkinson

the proposed test. Source: §14.18 Close the calibration record across the working interval (p. 8147)

- 11. Student H, adversarial challenge and confounding alternatives: For the precise observation involving A certificate covers the receiver but not the selected gain state, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Question Student G about a specific artifact or uncontrolled variable. Demand a control experiment that would expose a false positive or incorrect source attribution. Source: §14.8 Calibrate noise without confusing it with detection (p. 8116)

- 12. Student G, revised experimental answer: Address Student H's confounding mechanism by revising the controlled test described in the preceding prompt. Design a discriminating experiment involving A certificate covers the receiver but not the selected gain state: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Say precisely what observation would lead the panel to retain, qualify or reject the conclusion. Source: §14.18 Close the calibration record across the working interval (p. 8147)

Copyright 2026, James M. Atkinson

- 13. Student I, uncertainty and inferential limits: Assess uncertainty and evidential scope for A certificate covers the receiver but not the selected gain state. Do not hide the gap under an arbitrary uncertainty allowance or infer coverage from serial identity Explain the relevant statistical or calibration uncertainty, the range of defensible claims, and why the question cannot be settled by visual appearance or a single unqualified reading. Source: §14.2 Attach calibration to a stated measurement result (p. 8105)

- 14. Student J, Socratic challenge to Student I: For the precise observation involving A certificate covers the receiver but not the selected gain state, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Ask Student I whether the proposed uncertainty statement accounts for the actual receiver state, sample coverage and possible instrumental artifacts. Request an explicit statement of what evidence would reverse the conclusion. Source: §14.8 Calibrate noise without confusing it with detection (p. 8116)

- 15. Student I, quantified and qualified reply: Assess uncertainty and evidential scope for A certificate covers the receiver but not the selected gain state. Do not hide the gap under an arbitrary uncertainty allowance or infer coverage from serial identity Respond point by point to Student J. Distinguish a verified observation from a

conditional inference and name the missing datum, sensitivity test or uncertainty term that limits confidence. Source: §14.2 Attach calibration to a stated measurement result (p. 8105)

- 16. Student K, authority and evidential discipline: Determine which authority, calibration and reporting safeguards apply to the particular claim about A certificate covers the receiver but not the selected gain state and How should a reviewer respond; exclude protections irrelevant to the scenario Question Student F about the custody and reproducibility of the proposed records and ask Student G whether the discriminatory test remains within authorised laboratory and field boundaries. Source: §14.1 Calibration Model and Traceability (p. 8104)

- 17. Peer panel, negotiated consensus and residual dissent: Draft a narrow consensus about “A certificate covers the receiver but not the selected gain state”, addressing “How should a reviewer respond”; specify the exact measurement or evidential gap on which the speakers still differ Require Students A, B, D, G and I to respond to at least one objection raised by another speaker before voting. Record both the narrow agreement and the specific contested proposition that remains unresolved. Source: §14.18 Close the calibration record across the working interval (p. 8147)

Copyright 2026, James M. Atkinson

- 18. Moderator, reasoned disposition and follow-up: Record a final recommendation on “A certificate covers the receiver but not the selected gain state. How should a reviewer respond”, specifying the next test, responsible measurement record and limit of the conclusion Summarise the strongest evidence for and against the resolution of “A certificate covers the receiver but not the selected gain state. How should a reviewer respond”. Allocate the next measurement and documentary action to named student roles, and require each participant to distinguish accepted evidence from an unsupported assertion. V011-C14-DISCUSSION-025. What would make the chapter's calibration record independently reproducible by another analyst?

- 01. Moderator, opening proposition: Introduce the exact dispute, “What would make the chapter's calibration record independently reproducible by another analyst?” Put this particular dispute to the panel: What would make the chapter's calibration record independently reproducible by another analyst. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §14.18 Close the calibration record across the working interval (p. 8147)

- 02. Student A, terminology and scope: Agree the operational meanings of make, calibration, record and independently, reproducible, analyst in “What would make the chapter's calibration record independently reproducible by another analyst”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §14.18 Close the calibration record across the working interval (p. 8147)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of What would make the chapter's calibration record independently reproducible by another analyst; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §14.11 Declare the decision rule before seeing the result (p. 8122)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Declare the decision rule before seeing the result”. Require reconstruction of both arithmetic and validity rather than only matching the final number Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §14.11 Declare the decision rule before seeing the result (p. 8122)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of What would make the chapter's calibration record independently reproducible by another

analyst; explain what each record can establish State what the existing record establishes, what it does not establish, and which further measurement would change your opinion. Source: §14.2 Attach calibration to a stated measurement result (p. 8105)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “Declare the decision rule before seeing the result”. Require reconstruction of both arithmetic and validity rather than only matching the final number Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §14.11 Declare the decision rule before seeing the result (p. 8122)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. Provide raw observations, actual state and planes, correction values and versions, source certificates, covariance and domains, coverage convention, rule and result Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate between them without changing the measurand. Source: §14.18 Close the calibration record across the working interval (p. 8147)

Copyright 2026, James M. Atkinson

- 08. Student D, answer to Student E: Design a discriminating experiment involving What would make the chapter's calibration record independently reproducible by another analyst: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §14.18 Close the calibration record across the working interval (p. 8147)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of What would make the chapter's calibration record independently reproducible by another analyst; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §14.2 Attach calibration to a stated measurement result (p. 8105)

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving What would make the chapter's calibration record independently reproducible by another analyst:

Chapter 14 Answer Keys and Guidance

The essay and discussion guidance below identifies expected mechanisms, methods and evidence. A defensible alternative conclusion must state its assumptions, reasoning and limitations.

Copyright 2026, James M. Atkinson

Essay Guidance

V011-C14-ESSAY-001 — Define the measurement equation and required inputs for two distinct results, such as terminal power and relative phase. Distinguish calibration, adjustment and verification, and explain traceability scope, configuration applicability and uncertainty without claiming traceability guarantees correctness.

Review: Chapter 14 — Attach calibration to a stated measurement result.

V011-C14-ESSAY-002 — Reproduce −86.70 dBm, identify the +0.20 residual and each loss/gain sign, predict the −72.40 dBm corrected receiver plane, and state linearity, mismatch and state assumptions. Explain how wrong-plane or duplicate corrections can survive valid component certificates.

Review: Chapter 14 — Build a correction chain with signs that can be checked.

V011-C14-ESSAY-003 — Specify levels, frequencies, band and gain-state boundaries, independently characterized source path, detector and bandwidth. Distinguish low-level statistical effects from compression/intermodulation and explain why fitting a single line does not validate every endpoint.

Review: Chapter 14 — Amplitude Response and Linearity.

V011-C14-ESSAY-004 — Define simultaneous input relationship, reference planes, phase branch, frequency sweep and delay model. Test actual reset/retune/sample-rate operations and distinguish within-record from inter-record repeatability. Include cable and reference-path uncertainty.

Review: Chapter 14 — Frequency, phase, and delay require their own observables.

Copyright 2026, James M. Atkinson

V011-C14-ESSAY-005 — Describe hot/cold inputs, raw powers, equal gain, settling, compression and mismatch requirements. Contrast with waveform-specific detection/miss trials and acquisition schedules, explaining why neither result uniquely substitutes for the other.

Review: Chapter 14 — Calibrate noise without confusing it with detection.

V011-C14-ESSAY-006 — Start from centered inputs and expand the squared linear combination. Retain signed cross terms, units and covariance admissibility. Explain why Gaussian assumptions and independence are unnecessary for the identity but may matter to separate coverage claims.

Review: Chapter 14 — Model 14B: exact covariance and local uncertainty propagation.

V011-C14-ESSAY-007 — Define the gradient at the input estimate and the linearized output, propagate covariance, and identify the neglected remainder. Discuss curvature, singularities and domain boundaries; distinguish an exact affine identity from an approximate nonlinear uncertainty.

Review: Chapter 14 — Model 14B: exact covariance and local uncertainty propagation.

V011-C14-ESSAY-008 — Compute 0.1032 dB^2 and 0.321248 dB under zero covariances, then the -0.0432 covariance term and 0.244949 dB result. Explain the amplifier coefficient sign, evidence needed for correlation, and prevention of shared-reference double counting.

Review: Chapter 14 — Use covariance and model sensitivity deliberately.

Copyright 2026, James M. Atkinson

V011-C14-ESSAY-009 — Use 34°−11°, independent 0.30°/0.40° residuals and common 0.80° contribution. Show 0.50° uncertainty by cancellation and by 0.73+0.80−2×0.64. State equal-coupling, common-state and unwrapped-branch conditions.

Review: Chapter 14 — Application 14B.5: cancel a shared phase reference correctly.

V011-C14-ESSAY-010 — Use 36°,100 MHz,0.20° and 10 kHz; derive signed sensitivities and 5.55646 ps. Explain the small denominator uncertainty, branch assumption, constant-delay scope and need for independent phase-repeatability evidence.

Review: Chapter 14 — Application 14B.6: propagate phase-slope delay uncertainty.

V011-C14-ESSAY-011 — Calculate the +0.70 dB correction and weighted endpoint variances, covariance and residual. Explain the 0.161419 dB uncertainty, evidence for the residual, and changes needed for uncertain fraction or extrapolation.

Review: Chapter 14 — Application 14B.7: retain endpoint covariance in a correction interpolation.

V011-C14-ESSAY-012 — Represent independent reading errors and one shared correction input, derive $0.30^2+\frac{0.40^2}{n}$, compute n = 16 and 64, and show the 0.30 dB limit. Explain why correlated readings, drift or averaging powers require a different model.

Review: Chapter 14 — Application 14B.8: identify the uncertainty that averaging cannot remove.

Copyright 2026, James M. Atkinson

V011-C14-ESSAY-013 — Derive covariance and 0.00058 nW^2 difference variance; use bounded uniforms to establish positive support. Calculate −65.228787 dBm and 0.348640 dB local uncertainty. Distinguish exact affine difference, exact transformed support and approximate log dispersion.

Review: Chapter 14 — Application 14B.9: subtract paired powers before propagating a logarithm.

V011-C14-ESSAY-014 — Derive E[P] and Var(P) from Gaussian moments, compare μ10 mV and μ0 with σ1 mV,R50 ohms, and identify the omitted curvature term. Explain why multiplying a zero local uncertainty by a coverage factor cannot restore information.

Review: Chapter 14 — Application 14B.10: expose a zero-sensitivity failure of the local law.

V011-C14-ESSAY-015 — Use −86.70±0.49 dBm and −86.50 dBm to establish overlap and indeterminacy. Distinguish central estimate, uncertainty, coverage and decision, and describe legitimate follow-up without shifting the limit retrospectively.

Review: Chapter 14 — Declare the decision rule before seeing the result.

V011-C14-ESSAY-016 — Discuss explicit shared inputs versus derived covariance, signed coefficients, unit consistency, symmetry and positive semidefiniteness. Explain why individually plausible pairwise correlations and a favorable final total are insufficient evidence.

Review: Chapter 14 — Model 14B: exact covariance and local uncertainty propagation.

Copyright 2026, James M. Atkinson

V011-C14-ESSAY-017 — Use the power-difference or Gaussian-square examples to distinguish dispersion, coverage convention and possible-domain statements. Explain why factor two and positive central estimates do not establish universal coverage or positivity.

Review: Chapter 14 — Application 14B.9: subtract paired powers before propagating a logarithm.

V011-C14-ESSAY-018 — Record correction versions, serial applicability, units, interpolation and uncertainty. Tie checks to likely failures and consequential changes, distinguish targeted recharacterization from full recalibration, and define treatment of a failed closing reference.

Review: Chapter 14 — Calibration Lifecycle and Change Control.

V011-C14-ESSAY-019 — Explain how a shared faulty correction can reproduce its own error, retain raw comparisons and independent recomputation, and use opening, closing and change-point checks. Preserve affected data and justify any retrospective correction by evidence.

Review: Chapter 14 — Close the calibration record across the working interval.

V011-C14-ESSAY-020 — Explain why a room-temperature correction may not apply after 35°C warming, how a characterized correction can reduce 2.8 dB discrepancy to 0.6 dB, and why agreement within combined uncertainty is a bounded consistency result rather than proof of exact identity.

Review: Chapter 14 — Hypothetical Case Adjudication: Calibration, Gain, Amplitude and Phase Accuracy, Noise Figure, and Uncertainty.

Copyright 2026, James M. Atkinson

V011-C14-ESSAY-021 — Distinguish complex linear correction, repeatability and calibration uncertainty, shared calibration/comparison reference, and remaining nonlinear scope. Do not claim the study validates hypothetical configurations elsewhere in the book.

Review: Chapter 14 — System-Level Vector Calibration and Uncertainty.

V011-C14-ESSAY-022 — Require the measurement function, input domains, distributions, dependence and admissible covariance. Examine boundaries and curvature, compare simple analytic checks where available, and explain that numerical precision does not establish the assumptions.

Review: Chapter 14 — Use covariance and model sensitivity deliberately.

V011-C14-ESSAY-023 — Distinguish an applied correction's residual uncertainty from a wrong cable, wrong sign or unapplied offset. Use a decision-near-limit case to show the effect on central value and identify independent reconstruction checks.

Review: Chapter 14 — Attach calibration to a stated measurement result.

V011-C14-ESSAY-024 — For level, link raw indication, planes, state, correction terms, certificates, covariance, coverage and rule. For noise, retain linear hot/cold powers and temperatures, ratio/domain and gain checks. Make another analyst able to reproduce the arithmetic and its validity conditions.

Review: Chapter 14 — Close the calibration record across the working interval.

Copyright 2026, James M. Atkinson

V011-C14-ESSAY-025 — Explain equal-coupling cancellation in the difference, persistence in an average, and hidden common error in apparent agreement. Use signed measurement equations and stated dependencies rather than treating every shared reference as either always helpful or always harmful.

Review: Chapter 14 — Model 14B: exact covariance and local uncertainty propagation.

Copyright 2026, James M. Atkinson

Discussion Guidance

V011-C14-DISCUSSION-001 — Identify the omitted scope, request targeted characterization or narrow the claim, and retain the valid covered calibration. Do not hide the gap under an arbitrary uncertainty allowance or infer coverage from serial identity.

Review: Chapter 14 — Attach calibration to a stated measurement result.

V011-C14-DISCUSSION-002 — Resolve the configuration mismatch and recompute with applicable data. Explain why a precise uncertainty propagation cannot repair the wrong measurement equation or input identity.

Review: Chapter 14 — Attach calibration to a stated measurement result.

V011-C14-DISCUSSION-003 — Check correction signs, planes, instrument-applied terms, units and duplicate ownership against raw data. Keep physical linearity and mismatch checks separate from arithmetic closure.

Review: Chapter 14 — Build a correction chain with signs that can be checked.

V011-C14-DISCUSSION-004 — Inspect individual data and define a supported range; test boundaries and state transitions. Explain that an average fit statistic can conceal systematic endpoint behavior relevant to the intended measurement.

Review: Chapter 14 — Amplitude Response and Linearity.

Copyright 2026, James M. Atkinson

V011-C14-DISCUSSION-005 — Frequency-dependent phase/amplitude response, branch and interpolation, delay model and state repeatability. Acknowledge the valid single-frequency result while limiting its broader implication.

Review: Chapter 14 — Frequency, phase, and delay require their own observables.

V011-C14-DISCUSSION-006 — Identify common and canceling reference errors and compare against an independent suitable standard where needed. Agreement constrains relative behavior but can retain common absolute error.

Review: Chapter 14 — Frequency, phase, and delay require their own observables.

V011-C14-DISCUSSION-007 — State demonstrated frequency lock and within-record behavior separately from absent inter-record coherence. Require actual reset-state phase tests before combining acquisitions coherently.

Review: Chapter 14 — Frequency, phase, and delay require their own observables.

V011-C14-DISCUSSION-008 — No; repeatability does not supply equal gain. Preserve raw states, characterize the transfer or use a supported expanded model, and check hot-state compression and mismatch.

Review: Chapter 14 — Calibrate noise without confusing it with detection.

V011-C14-DISCUSSION-009 — Test the actual waveform, duration, threshold and observation schedule, retaining misses and detections. Distinguish acquisition opportunity and decision behavior from the noise budget.

Review: Chapter 14 — Calibrate noise without confusing it with detection.

Copyright 2026, James M. Atkinson

V011-C14-DISCUSSION-010 — Request the actual shared calibration model or measured dependency and check matrix admissibility. Recompute with supported assumptions; uncertainty is not optimized to obtain a preferred decision.

Review: Chapter 14 — Use covariance and model sensitivity deliberately.

V011-C14-DISCUSSION-011 — Reject the inconsistent joint covariance description, identify conflicting dependencies and reconstruct a physical model. Pairwise bounds are necessary but not sufficient.

Review: Chapter 14 — Model 14B: exact covariance and local uncertainty propagation.

V011-C14-DISCUSSION-012 — Show the double counting and rebuild either explicit common-input or consistent derived-covariance representation. Check signed coefficients and compare both formulations as an audit.

Review: Chapter 14 — Use covariance and model sensitivity deliberately.

V011-C14-DISCUSSION-013 — Separate branch ambiguity from local dispersion, establish the branch with suitable frequency/continuity evidence, and preserve the conditional result without claiming the uncertainty chooses the branch.

Review: Chapter 14 — Application 14B.6: propagate phase-slope delay uncertainty.

V011-C14-DISCUSSION-014 — Request measured between-point response or a supported smoothness bound. Distinguish endpoint calibration uncertainty from response-model inadequacy and consider uncertain frequency position or extrapolation.

Review: Chapter 14 — Application 14B.7: retain endpoint covariance in a correction interpolation.

Copyright 2026, James M. Atkinson

V011-C14-DISCUSSION-015 — Use the common-calibration model to explain 0.316228 to 0.304138 dB and the 0.30 dB floor. Determine whether a better reference or correction would address the dominant term rather than merely repeating readings.

Review: Chapter 14 — Application 14B.8: identify the uncertainty that averaging cannot remove.

V011-C14-DISCUSSION-016 — Retain the linear difference and investigate model and interpretation before assigning a log-domain uncertainty. Do not use an absolute-value transform or a central positive log to hide the boundary.

Review: Chapter 14 — Application 14B.9: subtract paired powers before propagating a logarithm.

V011-C14-DISCUSSION-017 — Use the exact squared-Gaussian moments to show 20 nW mean and 28.2843nWSD for 1 mV/50 ohms. Identify the missing curvature term and require a suitable nonlinear treatment.

Review: Chapter 14 — Application 14B.10: expose a zero-sensitivity failure of the local law.

V011-C14-DISCUSSION-018 — State the factor and distribution/uncertainty justification explicitly, distinguish adequate normal approximations from other domains, and avoid assigning unsupported coverage.

Review: Chapter 14 — Declare the decision rule before seeing the result.

V011-C14-DISCUSSION-019 — Calculate both endpoints, report indeterminate, preserve the result and explain follow-up targeting dominant uncertainty. Do not equate overlap with proof of exceedance or silently switch to a central-value rule.

Review: Chapter 14 — Declare the decision rule before seeing the result.

Copyright 2026, James M. Atkinson

V011-C14-DISCUSSION-020 — Keep the original rule and outcome; any later rule must be explicitly new with its rationale. Additional measurements should address the measurement purpose rather than rewrite the original decision.

Review: Chapter 14 — Declare the decision rule before seeing the result.

V011-C14-DISCUSSION-021 — Review affected processing and state scope, check representative raw and independently recomputed results, and retain or update files only with applicability evidence. Self-test has a narrower scope.

Review: Chapter 14 — Calibration Lifecycle and Change Control.

V011-C14-DISCUSSION-022 — Use the last valid check and documented change time, retain all data, and investigate whether evidence supports a narrower interval or bounded correction. Avoid uniform retrospective reassignment.

Review: Chapter 14 — Close the calibration record across the working interval.

V011-C14-DISCUSSION-023 — Identify shared errors and retained covariance, distinguish repeatability from full uncertainty, and seek independent evidence for claims requiring absolute validation. Agreement is useful within its dependencies.

Review: Chapter 14 — System-Level Vector Calibration and Uncertainty.

V011-C14-DISCUSSION-024 — The input dependence model is unsupported; reconstruct the common contribution and rerun if necessary. More trials improve numerical propagation but do not cure incorrect assumptions.

Review: Chapter 14 — Use covariance and model sensitivity deliberately.

Copyright 2026, James M. Atkinson

V011-C14-DISCUSSION-025 — Provide raw observations, actual state and planes, correction values and versions, source certificates, covariance and domains, coverage convention, rule and result. Require reconstruction of both arithmetic and validity rather than only matching the final number.

Review: Chapter 14 — Close the calibration record across the working interval.

Copyright 2026, James M. Atkinson

Chapter Glossary

ADJUSTMENT: An intervention intended to change a measuring system's response to the required relation. It is distinct from calibration, which establishes a relationship and its uncertainty, and verification, which checks a stated requirement. A changed response can require new characterization before previous corrections or uncertainty statements are used.

AFFINE MEASUREMENT FUNCTION: A measurement relation consisting of a constant plus a fixed linear combination of the input quantities. Its output mean and variance follow exactly from the input mean and covariance when the required second moments exist. Neither independence nor normality is required for that identity; the coefficients retain their signs and units.

AFFINE UNCERTAINTY PROPAGATION: Exact evaluation of output variance for a fixed affine measurement function from finite input second moments and their covariance.

CALIBRATION: An operation establishing, under specified conditions, the relationship between reference values and indications with their associated uncertainties, enabling a measurement result to be obtained from an indication. It is distinct from changing instrument settings or checking a requirement. Its relevance depends on the particular quantity, state, range and reference plane being reported.

Copyright 2026, James M. Atkinson

CALIBRATION CHANGE CONTROL: The identification and evaluation of changes that may invalidate a correction or its uncertainty statement. Firmware, processing, accessories, reference planes, gain states and remote power arrangements can alter applicability. Evidence about the affected quantities determines whether targeted recharacterization suffices; an unchanged certificate or successful self-test is not enough by itself.

CALIBRATION SCOPE: Quantities, ranges, states, reference planes, and conditions for which calibration results and uncertainties apply.

COMBINED STANDARD UNCERTAINTY: The standard uncertainty assigned to the measurement result after the relevant input contributions and dependencies have been propagated through the measurement model. The chapter's affine variance relation is exact under its finite-moment premises; using the same form for a nonlinear function additionally requires a justified local approximation.

COMMON CALIBRATION CONTRIBUTION: An input uncertainty shared across several observations, whose effect depends on its coupling and the signed coefficients of the reported quantity.

CORRECTION COVARIANCE: Joint uncertainty between correction inputs, retained with the signs of their measurement sensitivity coefficients.

Copyright 2026, James M. Atkinson

CORRECTION INTERPOLATION: Estimation of a correction between characterized points using a stated model and position. Endpoint uncertainty and covariance are distinct from the residual between the physical response and that interpolation model. An uncertain position, extrapolation or unresolved response structure changes the measurement equation and cannot be omitted merely because the file provides a smooth curve.

CORRELATION COEFFICIENT: A dimensionless normalized measure of covariance between quantities with nonzero standard deviations. Its contribution to output variance also depends on the signs of the measurement sensitivities. A favorable coefficient must be supported by the joint calibration model or evidence; it cannot be chosen to obtain a desired uncertainty or decision.

COVARIANCE MATRIX: The matrix of pairwise covariances of a specified input vector, with each entry carrying the product of the corresponding input units. A physically admissible matrix is symmetric and positive semidefinite. Separate plausible pairwise correlations need not form a valid complete matrix, so the joint model must be checked.

COVERAGE FACTOR: Multiplier applied to combined standard uncertainty to obtain an expanded uncertainty under a stated convention.

COVERAGE PROBABILITY: The probability assigned to an interval under a justified output-distribution and uncertainty interpretation. Multiplying standard uncertainty by two does not independently establish a universal probability. Such interval coverage is also distinct from the false-alarm or detection probabilities of a receiver search procedure.

Copyright 2026, James M. Atkinson

CURVATURE BIAS: The difference arising when the expected output of a nonlinear transformation differs from the transformation evaluated at the expected input. The squared-voltage example exhibits this mean shift explicitly. It is a model consequence, not evidence of an instrument fault, and its significance depends on the intended accuracy of the reported result.

DECISION RULE: The declared procedure translating a measurement result and its uncertainty into an outcome relative to a requirement. It can specify acceptance, rejection and an indeterminate region. The rule should be selected before observing the result and retained with it; changing the rule later creates a different decision rather than revising the earlier evidence.

DETERMINISTIC ERROR BOUND: A justified limit on the magnitude or allowed set of an error under specified conditions. It differs from a standard deviation, which describes dispersion under an uncertainty model. Converting one into the other requires additional information; a multiple of standard uncertainty is not automatically a worst-case enclosure.

EXPANDED UNCERTAINTY: Combined standard uncertainty multiplied by a stated coverage factor, with the basis of the associated coverage interpretation identified.

GRADIENT: The set of first partial derivatives of a scalar measurement function at a declared input point. These signed, dimensioned sensitivities define its local linear approximation. They can propagate input covariance locally, but a small or zero derivative does not show that curvature or a nearby domain boundary is negligible.

Copyright 2026, James M. Atkinson

GUARD BAND: Decision margin used to account for uncertainty near an acceptance or compliance limit.

INDETERMINATE RESULT: An outcome in which the supplied evidence does not meet the stated conditions for either acceptance or rejection. In the chapter's constructed rule, an uncertainty interval overlapping the upper limit has this status. It neither proves compliance nor proves that the actual quantity exceeds the limit.

INDICATION: The value supplied by the measuring system before any additional external corrections needed for the stated result. Its quantity, units, detector and processing state must be identified. A numerically plausible indication can still be inconsistent with the intended reference plane or already contain a correction that should not be applied again.

INPUT SUPPORT: The complete set of values permitted by the stipulated joint input model. It can determine whether a nonlinear operation is defined throughout the problem. The paired-power example proves a positive difference over its full support before applying a logarithm; a positive central estimate alone would not establish that property.

INTERMEDIATE CHECK: Reference observation between calibrations used to test continued validity for a stated quantity and configuration.

INTERPOLATION RESIDUAL: Difference between a physical response and the adopted interpolation model, characterized separately from uncertainty in the endpoint values.

LOCAL PROPAGATION ADEQUACY: Suitability of a first-order uncertainty approximation for the stated input domain and intended output, including the effect of neglected curvature and boundaries.

Copyright 2026, James M. Atkinson

LOGARITHMIC UNCERTAINTY PROPAGATION: Propagation through a logarithmic transformation of a strictly positive quantity using the appropriate model and sensitivity. The chapter separates exact variance of a linear power difference from the local variance of its logarithm. Exact transformed limits can be asymmetric, and a domain admitting zero or negative power differences requires a different treatment.

MEASURAND: The quantity selected for measurement and reporting, with the conditions needed to distinguish it from related quantities. Receiver-terminal power, field strength, relative phase and detection probability require different models. Defining that intended result before selecting corrections and calibrations prevents the available instrument display from silently determining the measurement question.

MEASUREMENT CORRECTION: A compensation applied for an identified effect in the measurement model. Its sign follows the physical relationship and its uncertainty remains in the result. A known significant offset should not be concealed merely by widening an uncertainty interval, and a correction already applied by the instrument must not be counted twice.

MEASUREMENT MODEL: Equation or functional relationship connecting the measurand to input quantities.

MISMATCH UNCERTAINTY: Uncertainty caused by unknown or varying phase relationships among reflected waves at imperfectly matched interfaces.

Copyright 2026, James M. Atkinson

NONLINEAR REMAINDER: The part of a nonlinear measurement response omitted by its local linear approximation. The suitability of first-order propagation depends on whether that omitted behavior matters over the actual input domain. Near a singularity, boundary or zero derivative, it can change the output dispersion or shape even when the central calculation is finite.

REFERENCE CANCELLATION: Removal of a shared contribution by the signed structure of a reported difference when its coupling is genuinely identical in both observations. The phase example obtains the same result by an explicit common input or a consistent covariance matrix. Unequal paths, changed states or unresolved phase branches invalidate automatic cancellation.

REPEATABILITY CONTRIBUTION: The uncertainty contribution associated with variation among observations made under the declared repeated conditions. Averaging can reduce a suitable independent reading-error contribution, but not an unchanged shared calibration input. A repeatability-only estimate can therefore understate the uncertainty of a corrected system-level result.

SENSITIVITY COEFFICIENT: Local derivative of the measurement function with respect to an input quantity, carrying the units and sign needed for uncertainty propagation.

STANDARD UNCERTAINTY: An uncertainty expressed in the form of a standard deviation under the stated input information and model. It describes dispersion rather than a guaranteed maximum error. Its numerical value alone does not define a coverage probability, a detection probability or an acceptance decision.

Copyright 2026, James M. Atkinson

SYSTEM-LEVEL VECTOR CALIBRATION: Calibration of the relevant complex response of an assembled measurement system, retaining amplitude, phase and their uncertainty relationships. The cited experiment combines multiple correction contributions and correlations. Its success illustrates a method under the published conditions, without certifying another receiver configuration or bounding that configuration's remaining nonlinear behavior.

TRACEABILITY: Property of a measurement result relating it to references through a documented, unbroken chain of calibrations with stated uncertainties.

UNCERTAINTY BUDGET: An organized account of the input quantities, uncertainty information, sensitivities and dependencies relevant to a specified result. The table follows the measurement model rather than replacing it. Shared references, unapplied corrections, interpolation residuals and configuration mistakes must be treated according to their actual roles instead of being assigned arbitrary independent rows.

VERIFICATION: A check that specified requirements are met using appropriate evidence for the quantity, configuration and time concerned. A field reference can verify present function within its traversed scope without replacing a full calibration. Successful internal checks do not automatically establish external-path transfer, file correctness or uninterrupted validity over an earlier interval.

The research concerns complex-vector calibration or noise-temperature measurement where amplitude, phase and uncertainty propagate through the measurement chain. Reference-plane consistency, added cable paths and calibration-state changes are material to a repeatable comparison. Published experimental results cannot automatically be transferred to a different apparatus or treated as certification of the book’s constructed numerical examples. Its use here is bounded by the physical reference plane, implementation version and the evidentiary proposition being tested.

Chapter 15. Triggering, Burst Capture, Recording, Metadata, and Reproducibility

Copyright 2026, James M. Atkinson

15.1 Probability of Intercept and Observation Strategy

An intermittent signal can be missed by a receiver that is sufficiently sensitive but observes the wrong time, frequency, antenna, or state. Probability of intercept depends on signal duty cycle, dwell, revisit time, instantaneous bandwidth, trigger threshold, number of sensors, and search schedule. A sweep that covers a wide span slowly may have poor probability for short bursts, while a wideband recorder can preserve the event at the cost of data rate and dynamic range.[9]

The survey plan matches observation architecture to the hypothesized signal behavior. Continuous carriers, periodic bursts, frequency hopping, wake-up transmissions, event-triggered devices, and remotely illuminated responses require different strategies. Controlled state changes, repeated occupancy windows, and synchronized external observations improve efficiency. Missed observations are interpreted within the coverage model rather than as proof of absence.

15.2 Model 15A: calculate conditional event coverage from usable windows

An observation schedule should be expressed in intervals during which the required data are actually usable. A tuning command, an illuminated acquisition indicator, and a saved record can describe different intervals. Frequency settling, filter memory, AGC recovery, trigger rearming, transfer pauses, and invalid sample flags can shorten the usable part of a nominal dwell. The event criterion then states how much contiguous signal must be present in one valid record. Detecting that a burst occurred, measuring its steady amplitude, estimating its modulation, and preserving its complete startup can require different lengths from the same event.

Copyright 2026, James M. Atkinson

Figure 79. Burst timing and missed observation windows.

Model 15A isolates this timing geometry. It does not infer a detector threshold, false-alarm rate, signal-to-noise ratio, or ability to recognize the waveform. Those are prerequisites established by separate receiver tests. The model assumes that an event meeting those prerequisites is

Copyright 2026, James M. Atkinson

successfully available whenever one usable record overlaps it for at least the specified positive duration. Calling the result conditional capture probability keeps the geometric claim separate from an untested detection claim. Real-time analyzer descriptions likewise tie transient capture to acquisition bandwidth, processing continuity, event duration, and the quantity being measured.[10]

Equation 30A. Periodic usable-window and event definitions

$$T>0, 0<b<T, 0<D_j<T, r>0$$
$$W_j=[a_j, a_j+D_j], event=[s, s+b]$$

All times and durations in one calculation use the same unit, seconds or explicitly converted milliseconds. Index j labels a usable window W_j with start a_j and length D_j. The set E_j contains its eligible event starts, π_T reduces starts modulo the period, and A is the merged eligible-start set within one period. Its length is a duration, so length divided by T is a dimensionless probability. The random start phase S is distinct from the deterministic trial start s.

Let the observation schedule repeat with positive period T. Each declared usable window is a single contiguous acquisition interval with length strictly between zero and T. An event has length b strictly between zero and T. Its start phase S is considered modulo T, and the required contiguous overlap r is positive. Windows may cross the arbitrary period origin. Keep such a

10 Rohde & Schwarz, R&S ESW EMI Test Receiver User Manual, 1177.6298.02, version 18 (2025), §§9.7.1.2–9.7.1.3, 193–94, https://scdn.rohde-schwarz.com/ur/pws/dl_downloads/pdm/cl_manuals/user_manual/1177_6298_01/ESW_UserManual_en_18.pdf; MACOM, “Designing with Diodes: Protecting Sensitive Components” (September 2, 2022), receiver-protector operation and recovery discussion, https://www.macom.com/updates/articles/2022/designing-with-diodes-protecting. These are identified examples of preselection, gain placement, and protection, not a universal front-end architecture or an instrument-independent limit.

Copyright 2026, James M. Atkinson

record intact on an unfolded time axis before reducing its eligible event starts modulo T. Two files are not one continuous record merely because their timestamps appear adjacent; continuity must be established before joining them.

For one usable window from a to a plus D, consider an event from s to s plus b. Their intersection length is the positive part of the smaller ending time minus the larger starting time. Requiring at least r seconds of overlap is impossible when either the event or window is shorter than r. Otherwise the event must start no earlier than a plus r minus b and no later than a plus D minus r. These two inequalities give the complete eligible-start interval. They are derived on the unfolded axis, where the meaning of one contiguous overlap is unambiguous.

Equation 30B. Contiguous intersection length

$$O(s)=max(0,min(s+b,a+D)-max(s,a))$$

Equation 30C. Eligible starts for one contiguous window

$$E_j=[a_j+r-b,a_j+D_j-r]\,if\ r\leq min(b,D_j)$$
$$E_j=\varnothing\ otherwise$$

For a periodic schedule, reduce each eligible-start interval modulo T and take their union. When an interval crosses zero, its two pieces on the displayed period still represent one set of eligible starts. Measure the union only after overlapping pieces have been merged. Adding the lengths of individual windows or their eligible-start sets can count the same event phase more than once. The union calculation also handles windows that differ in length or are separated by acquisition dead time.

Copyright 2026, James M. Atkinson

Equation 30D. Capture-start union on one schedule period

$$A = \bigcup_j \pi_T(E_j)$$

$$\pi_T(s) = s - T\lfloor \frac{s}{T} \rfloor, A \subset ¿$$

¿

If the event start is uniformly distributed over one period, conditional capture probability is the length of that union divided by T. Uniformity is a model of the event phase relative to the schedule, not a consequence of ignorance about it. A synchronized device, a periodic telemetry source, or a common clock can produce a concentrated or fixed phase. In those circumstances use the actual phase distribution or a deterministic coverage statement. A plausible average over hypothetical start phases does not establish the outcome at the phase encountered in a particular survey.

Equation 30E. Uniform-start conditional capture probability

$$S \sim Uniform ¿$$

¿

For one window, the eligible interval has length D plus b minus twice r when the overlap requirement is feasible. Reduction modulo T caps its union length at T. The resulting compact expression is useful, but only with the stated domain. In particular, setting r equal to zero would make an empty intersection satisfy an unhelpful greater-than-or-equal test. A point observation is treated separately: an ideal instantaneous event must fall within a usable window. Its probability is D divided by T for one window, which is also the appropriate short-event limit when the entire shrinking event is required.

Copyright 2026, James M. Atkinson

Equation 30F. Single-window result with its feasibility condition

$$p = min\left(1, \frac{D + b - 2r}{T}\right) if\ 0 < r \leq min(b, D)$$
$$p = 0\ if\ r > min(b, D)$$

Equation 30G. Ideal point observation as a separate limit

$$p_{point} = \frac{D}{T}, instantaneous\ event\ inside\ the\ usable\ window$$

The strict window-length condition excludes a continuously usable acquisition represented as repeated touching pieces. If acquisition genuinely continues through each period boundary, merge those pieces and evaluate the actual continuous record. If a real rearm gap exists, preserve the gap. This distinction is material when the criterion requires one uninterrupted portion of a burst: two short pieces on either side of a gap do not become one longer observation by adding their durations.

Repeated trials require a second, separate probability assumption. If event phases are independent and identically distributed with single-trial probability p, the probability of at least one capture is one minus the probability that all trials miss. Independence must concern the relevant event phase and usable schedule, not merely the number of files. A periodic event at a fixed phase can miss the same window indefinitely. Changing the schedule, observing continuously, or introducing justified independent phase variation changes that experiment; repeating the original schedule does not.

Equation 30H. Independent repeated trials

$$P_{\geq 1} = 1 - (1 - p)^n$$
$$n \in \mathbb{Z}_{\geq 1}, trials\ independent\ with\ common\ p$$

Copyright 2026, James M. Atkinson

For a desired probability strictly between zero and one and a single-trial probability strictly between zero and one, solving the complement inequality gives an integer minimum trial count. Round upward and verify the preceding integer so the boundary is explicit. If p is zero, no finite positive count reaches a positive target. If p is one, one valid trial suffices. A target of exactly one is unattainable in finitely many independent trials when p remains strictly between zero and one. These endpoint statements prevent a logarithmic formula from being applied outside its domain.

Equation 30I. Minimum independent trial count for an interior target

$$n_{min} = \lceil \frac{\ln(1-q)}{\ln(1-p)} \rceil$$
$$0 < p < 1, 0 < q < 1$$

Independent trials with different known probabilities use the product of their individual miss probabilities. This extension can represent a deliberately varied schedule only if the corresponding independence assumptions remain justified. Correlated trials require their joint distribution, or a defensible bound, rather than the same product with new labels. The practical record should preserve the schedule and event model so a reviewer can distinguish a calculated coverage probability from a count of observations.

Equation 30J. Independent trials with unequal probabilities

$$P_{\geq 1} = 1 - \prod_{i=1}^{n} (1 - p_i), \textit{independent trials}$$

Copyright 2026, James M. Atkinson

15.3 Worked applications with hypothetical inputs

Copyright 2026, James M. Atkinson

15.4 Application 15A.1: Distinguish a point observation from full capture of a short event

A schedule repeats every 100 ms and has one usable window from 10 through 30 ms. An ideal point event with uniform start phase is captured with probability $\frac{20}{100}$, or 0.20. A finite 0.1 ms event that must be captured completely instead has eligible starts from 10 through 29.9 ms. Its conditional probability is 0.199. The small difference comes from the trailing edge of the complete-event requirement.

This example distinguishes a point limit from a finite record criterion. It does not set an actual receiver minimum pulse width. A detector, channel filter, or amplitude estimator may need a much longer signal than 0.1 ms. Establish that prerequisite first, then use the corresponding usable interval and event requirement in the geometry. Endpoints have zero probability under the stipulated continuous uniform distribution, although an exact deterministic start still needs a consistent boundary convention.

Copyright 2026, James M. Atkinson

15.5 Application 15A.2: Capture a burst when only part of it is required

Keep the 100 ms period and the 10–30 ms usable window, but use a 5 ms event and require only one contiguous millisecond. Equation 30C gives starts from $10+1-5$ ms $=6$ ms through $30-1$ ms $=29$ ms. The eligible interval is 23 ms long, so conditional capture probability is 0.23. An event may begin before the window and still provide the required observed tail.

The increase beyond the 0.20 point-event probability does not mean the receiver observes longer than its 20 ms dwell. The finite burst can overlap the dwell even when its start lies outside it. The calculation is appropriate only if the stipulated one millisecond is sufficient for the intended observation and any leading transient or settling requirement has already been accounted for. It does not establish complete-event recording.

Copyright 2026, James M. Atkinson

15.6 Application 15A.3: Require the whole burst

Now require the whole 5 ms event in the same 10–30 ms window. Eligible starts run from 10 through 25 ms, giving probability 0.15. Compared with Application 15A.2, the event and schedule are unchanged; only the evidence requirement has changed. Capturing an identifiable fragment and preserving the entire burst are therefore different coverage claims.

A report should state which claim its probability describes. If a later analysis needs startup timing, pulse count, or a complete modulation frame, a survey planned only for a short fragment may not provide it. Preserve incomplete records as observations, but do not relabel them as complete captures after seeing a recognizable pattern. A prospective criterion makes both the success and the limitation reviewable.

Copyright 2026, James M. Atkinson

15.7 Application 15A.4: Reject an impossible overlap requirement

A 100 ms schedule contains a usable interval from 10 through 14 ms. The event lasts 2 ms, while the requested contiguous observation is 3 ms. Since the event itself is shorter than the requirement, the eligible-start set is empty and conditional probability is zero. A longer dwell or more repetitions cannot create a third millisecond within that event.

The appropriate response is to reconsider the measurement question or acquire a different kind of evidence. Combining separate events might support an estimator under an additional repeatability model, but it would no longer meet the stated one-event contiguous criterion. Treat that as a new justified analysis, not a successful application of the impossible original requirement.

Copyright 2026, James M. Atkinson

15.8 Application 15A.5: Remove settling and closing guards from nominal dwell

A nominal 0–30 ms dwell in a 100 ms schedule loses its first 4 ms to verified settling and its last 3 ms to a verified closing exclusion. The usable interval is 4–27 ms. For an 8 ms event requiring 2 ms of contiguous overlap, the unfolded eligible starts are −2 through 25 ms. Modulo the schedule period, they are 98–100 and 0–25 ms, giving probability 0.27. Ignoring the guards would give 0.34.

The guard lengths are stipulated measured exclusions, not assumed properties of every receiver. Test them with the actual tuning, gain, bandwidth, trigger, and recording path. A command log alone establishes when a change was requested, not when the data became valid. If settling depends on the previous state or signal level, retain the relevant transition class rather than applying one optimistic guard to every dwell.

Copyright 2026, James M. Atkinson

15.9 Application 15A.6: Take the union of overlapping capture-start sets

Use two usable windows, 10–25 and 28–43 ms, in a 100 ms schedule. A 20 ms event needs 5 ms of contiguous overlap in either single window. The first eligible-start interval is −5 through 20 ms and the second is 13 through 38 ms. Their union modulo 100 ms is 95–100 together with 0–38 ms, totaling 43 ms. Conditional capture probability is 0.43, while adding the two separate probabilities would incorrectly give 0.50.

The overlap from 13 through 20 ms corresponds to starts that can satisfy either window. Each is one event phase, so it contributes once to the probability of any qualifying record. The rule still does not add a short overlap in the first window to a short overlap in the second. If the scientific objective permits combining separated pieces, its coherence, repeatability, and estimator assumptions must be stated in a different record criterion.

Copyright 2026, James M. Atkinson

15.10 Application 15A.7: Keep a deterministic repeated miss deterministic

A 5 ms event always begins at phase 50 ms of the same 100 ms schedule. A usable window at 10–30 ms misses it on every repetition. One hundred events produce zero captures, despite the nonzero uniform-phase probability calculated for a different experiment in Application 15A.2. Moving the usable window to 49–69 ms gives a full 5 ms overlap and captures all one hundred stipulated events.

Neither count is a random estimate in this deterministic example. The fixed relationship between event and schedule controls the result. A survey that repeatedly observes a commensurate miss needs a changed timing strategy or a justified distribution of relative phases. More repetitions are useful only when they add coverage or evidence; the independence formula cannot convert identical geometric misses into new opportunities.

Copyright 2026, James M. Atkinson

15.11 Application 15A.8: Preserve one contiguous window across the period origin

A single continuous acquisition runs from 90 through 110 ms across the origin of a 100 ms schedule. The event lasts 15 ms and needs 12 contiguous milliseconds. Keeping the window intact gives eligible starts from 87 through 98 ms and probability 0.11. An event starting at phase 95 ms has a 15 ms overlap and qualifies. One starting at phase zero has only a 10 ms overlap with the relevant record and fails.

Splitting the acquisition at the displayed zero would incorrectly turn one 20 ms record into two 10 ms pieces, neither long enough to satisfy the 12 ms requirement. Conversely, joining records across a genuine acquisition gap would falsely create continuity. Period coordinates, file boundaries, and physical continuity are separate concepts. The metadata must identify which boundaries are merely representational and which interrupt the samples.

Copyright 2026, James M. Atkinson

15.12 Application 15A.9: Calculate repeated capture only under independent start phases

Under independent uniform start phases, use the single-trial probability 0.23 from Application 15A.2 for ten trials. The all-miss probability is 0.77 to the tenth power, or 0.073266805. The probability of at least one qualifying capture is 0.926733195. This is a conditional result for the declared timing and signal-validity assumptions.

Independence could be established by the event-generation protocol in a controlled test. It should not be inferred from a field log containing ten timestamps. Shared triggers, periodic operation, and synchronized observation can correlate those starts. If the trial structure changes after a missed event, preserve the adaptive rule and analyze the resulting experiment instead of reporting the original fixed-trial expression without qualification.

Copyright 2026, James M. Atkinson

15.13 Application 15A.10: Solve for a conditional trial count and check the boundary

For independent trials with probability 0.23, require at least 0.99 probability of one capture. Equation 30I gives a minimum of 18 trials. Their probability is 0.990946155; 17 trials give only 0.988241760. Checking both integers verifies the upward rounding at the acceptance boundary.

Eighteen trials are not a universal receiver-search prescription. They solve this particular conditional model with its stated event length, usable window, overlap requirement, and independent phase law. A different event population or a detector failure changes the inputs or invalidates the model. Preserve those conditions beside the number so a later reader can evaluate whether the trial count applies to the actual observation.

Copyright 2026, James M. Atkinson

15.14 Trigger Types and Pretrigger Context

Receivers may trigger on level, frequency mask, pulse width, edge, pattern, external event, time, GPS or network schedule, or software statistic. Each trigger has latency, dead time, hysteresis, false-alarm behavior, and a specific location in the chain. A trigger after narrow filtering cannot respond to out-of-band precursors; a trigger after AGC can be delayed or suppressed by control behavior.

Pretrigger memory preserves the context before the event and is essential for identifying startup transients, causal sequences, or preceding interference. Record length must include settling and recovery after the event. Trigger and acquisition clocks may differ, producing timestamp uncertainty. A trigger test with a known burst verifies latency, pretrigger depth, and missed-event behavior.

Copyright 2026, James M. Atkinson

Figure 80. Burst capture and reproducible analysis.

Copyright 2026, James M. Atkinson

15.15 Verify the trigger at its actual signal-path location

A trigger is an estimator operating somewhere in the receiver chain. Identify whether it sees the full-rate digitized signal, a decimated channel, a filtered detector, or a software statistic. Its bandwidth and latency can differ from those of the saved waveform. A brief event may pass through the recorder while failing the trigger, or satisfy a detector before enough valid waveform samples are available. The documented distinction between full-rate and decimated trigger paths in real-time instruments illustrates why a trigger label alone does not establish this relationship.[11]

Characterize trigger timing with a known stimulus that includes the relevant leading edge, duration, level, modulation, and prior quiet interval. Record the stimulus reference and the actual sample interval around the trigger. Vary pretrigger allocation and total record length while keeping the event definition fixed. Then examine retrigger, holdoff, and rearm behavior using event pairs at controlled separations. A successful isolated pulse does not test the second pulse that arrives during recovery.

15.16 Wideband Recording and Data Integrity

Wideband recording preserves flexible analysis but generates high data rates. Bit depth, sample rate, channel count, data type, headers, time stamps, compression, and storage performance determine file size and continuity. The recording path is monitored for dropped samples, overruns, packet loss, repeated blocks, clock unlock, thermal throttling, and file rollover. A hash is calculated for stable files after closure.

Copyright 2026, James M. Atkinson

Figure 83. I/Q bandwidth, bit depth and recording duration.

Segmented acquisition can reduce storage by capturing only triggered intervals, but it can bias occupancy and omit context. Continuous circular buffers with triggered extraction offer a compromise. File formats should preserve center frequency, sample rate, scaling, time reference, device

Copyright 2026, James M. Atkinson

identity, gain and filter states, and any processing. If metadata is stored separately, binding hashes or a controlled manifest maintain the relationship.

Copyright 2026, James M. Atkinson

15.17 Metadata, Time, and Site Context

Technical metadata includes instrument serial number, software and driver versions, antenna and path, calibration files, coordinates, orientation, height, operator, authority, environment, trigger settings, clock source, time uncertainty, and state of relevant systems. Human-readable notes explain why settings changed and identify unexpected conditions. Automated logs capture rapid configuration changes that an operator may not notice.

Absolute time can be less important than relative timing for some surveys, but the requirement should be explicit. Correlation with access-control events, device operation, power switching, network logs, or other sensors needs a common time basis and known uncertainty. Time-zone, leap-second, daylight-saving, and clock-correction behavior are documented. A timestamp without a clock history is not a complete timing measurement.

Copyright 2026, James M. Atkinson

15.18 Reproducible Analysis and Derived Products

Analysis scripts, software versions, parameters, calibration inputs, excluded intervals, and manual decisions are preserved. Derived spectra, audio, decodes, images, and tables identify the source file and processing chain. Where proprietary software prevents complete export, setup files, screenshots, command histories, and independent checks provide additional context.

Reproducibility is tested by rerunning the analysis on the same source, using a second implementation where practical, and applying the method to reference and noise-only data. Results sensitive to one threshold or one window are reported as such. Data minimization and access controls apply to the preserved records, especially where incidental communications content or personally identifiable information could be present.

Copyright 2026, James M. Atkinson

15.19 Bind sample continuity, storage accounting and derived results

Use Equation 29 with the stored representation, not only the converter resolution printed on a specification sheet. A nominal 12-bit component may occupy a 16-bit container; an integer format and a floating-point export can have different byte rates for the same sample sequence. State whether samples are real or complex, how channels are interleaved, the byte order, signedness, scaling, and any packing. Headers, padding, timestamps, compression, and rollover records require additional accounting beyond the payload equation.

Test sustained writing for the planned duration and configuration. Short benchmark bursts can be absorbed by buffers and conceal a slower steady storage path. Monitor sequence numbers, sample counters, block lengths, overrun indicators, and clock status. A file hash proves that the preserved bytes have not changed relative to that hash; it does not prove that the acquisition originally contained every intended sample. Continuity evidence must be produced by the acquisition and checked before spectral or timing interpretations depend on it.

Treat gaps and repeats as explicit sample-domain events. A missing block changes the relationship between index and elapsed time, while concatenating the remaining bytes can create a false discontinuity or erase the true interval. Model 10E provides the sample-index and phase-continuity framework, and Model 12A supplies the time-reference relationship. Preserve a gap map or equivalent sequence record and restrict analyses to

Copyright 2026, James M. Atkinson

valid segments when the estimator assumes uniform uninterrupted sampling.

A derived result should identify its source record, selected interval, channel, calibration, receiver state, sample scale, and processing parameters. Windowing and spectral normalization belong to Chapter 9; mixing and decimation belong to Chapter 10; modulation alignment belongs to Chapters 6 and 7. Record these decisions as part of the result rather than expecting a screenshot to convey them. A second implementation can then reproduce the same declared quantity and expose a convention mismatch instead of merely generating a visually similar plot.

Before releasing a negative coverage statement, reconcile what was planned, what was commanded, what the receiver marked valid, and what was successfully preserved. Report excluded intervals and untested event classes. A clean recording of one band cannot support a claim about a band outside the instantaneous passband, and a high capture probability for one event model does not establish absence of all other emissions. The useful conclusion is bounded by the actual acquisition and the question it was configured to answer.

Copyright 2026, James M. Atkinson

15.20 Coverage Review and Storage Governance

Coverage and storage plans are reviewed before deployment against expected event duration, revisit interval, trigger dead time, channel count, sample format, storage write speed, retention, and access restrictions. The plan includes reserve capacity and a response to lost packets or device failure. Long captures are divided through controlled rollover so that files remain manageable without losing chronology.

Data disposition is linked to the authorized purpose. Native records needed for evidence or later verification are preserved with access controls, while incidental or unnecessary content is minimized according to policy. Derived products do not silently replace the native capture, and deletion or migration events are documented.

Copyright 2026, James M. Atkinson

15.21 Quantitative Model for Triggering, Burst Capture, Recording, Metadata, and Reproducibility

Equation 3. Uncompressed I/Q data rate

$$R_{\text{data}} = \frac{f_s N_{\text{ch}} N_{\text{comp}} N_{\text{bits}}}{8}$$

Uncompressed byte rate R_{data} equals sample rate f_s times number of channels N_{ch}, components per channel N_{comp}, and bits per component N_{bits}, divided by eight. Headers, packet overhead, compression, and file-system behavior change the actual storage rate.

Equation 4. Independent-window intercept probability

$$P_{\text{intercept}} = 1 - \left(1 - p_{\text{hit}}\right)^{N_{\text{obs}}}$$

If N_{obs} observation windows are independent and each has probability p_{hit} of overlapping a signal event, total intercept probability follows the complement relation. Real revisit schedules and periodic signals often violate independence and require a specific timing model.

Equation 29 is byte accounting for the declared uncompressed format, including both I and Q when the component count is two. Its throughput must be verified against the actual recording path. Equation 30 is the independent-trial special case examined in Model 15A and Applications 15A.1–15A.10; correlated or phase-locked observation opportunities require their own timing calculation.

Copyright 2026, James M. Atkinson

Table 2. Chapter 15 receiver controls and interpretation limits

Control or quantity	Measurement or record	Interpretation value	Failure or limitation
Search coverage	Instantaneous bandwidth, dwell, revisit, duty cycle, sensors, and state windows	Quantifies probability of observing an intermittent signal	No observation outside the covered windows does not establish absence
Trigger	Location, statistic, threshold, latency, dead time, pretrigger, and test burst	Preserves relevant events and context	Trigger logic can miss or distort the event
Recording integrity	Rate, depth, packet sequence, overrun, clock, file rollover, storage, and hashes	Supports continuous and reproducible samples	Dropped samples can create false transients and spectral splatter
Metadata and analysis	Site, time, configuration, calibration, script, parameters, and derived-file lineage	Connects the data to a defensible method	A derived image without its source and settings is weak evidence

15.22 Hypothetical Applied Calculation: Triggering, Burst Capture, Recording, Metadata, and Reproducibility

A two-channel complex recorder samples at 40 MS/s with 16-bit I and 16-bit Q components. The uncompressed data rate is 320 MB/s. A 30-minute continuous capture requires about 576 GB before headers and file-system overhead, so storage margin and sustained-write testing are part of the survey plan.

Copyright 2026, James M. Atkinson

15.23 Hypothetical Case Adjudication: Triggering, Burst Capture, Recording, Metadata, and Reproducibility

A triggered receiver captures several unexplained bursts but omits the preceding 2 ms. Increasing pretrigger depth reveals that every burst follows a relay transition in the receiver's own antenna switch. The additional record establishes temporal order and supports a switch-related transient hypothesis. It does not yet distinguish that mechanism from a real signal newly admitted by the switch or another shared control. A matched-reference comparison with the switch held static or bypassed would test the explanation. The corrected configuration preserves both events and the unresolved attribution.

Copyright 2026, James M. Atkinson

15.24 Acquisition provenance, loss masks and portable complex-sample metadata

Copyright 2026, James M. Atkinson

The missing-data interval is unknown, not a run of zero-amplitude measurements. Preserve counter discontinuities, epoch, sample rate, state changes and an explicit sample-validity mask before spectral estimation.

Figure 84. Missing I/Q samples and false time labels.

Native I/Q samples cannot be understood independently of their numeric representation and acquisition-state history. A complex-sample stream has at minimum a declared signedness or floating-point datatype, endian convention, I/Q ordering, channel count, sample rate, centre frequency, scale and clock reference. An identical byte array can be interpreted as a

Copyright 2026, James M. Atkinson

radically different waveform if its manifest changes, even when a cryptographic digest of the sample payload remains unchanged. The SigMF v1.2.6 specification supplies a useful public vocabulary for recording metadata alongside datasets, including global recording information, capture segments and annotations. Conformance to a metadata syntax, however, is not a substitute for calibrated proof that the recorded analogue input represented a particular electromagnetic event. The missing-sample timeline example is illustrated in Figure 70.

A capture manifest should contain state transitions as separate entries where they affect the data. The fields describing a later retune, gain change or receiver selection cannot silently be inherited when the specification requires explicit capture metadata. Record the actual start sample index, actual frequency and rate as known from instrument status, and any uncertain transition boundaries. File creation time, acquisition start and sample aperture time are not generally interchangeable. A simple time estimate for contiguous uniform samples is $t_k = t_0 + k/f_s$, with t_0 a defined aperture reference and f_s the established acquisition rate. When samples were lost, concatenating the surviving bytes and applying the same expression to the new ordinal index shifts the subsequent physical-time mapping. A gap mask or original acquisition counter is needed to retain the missing duration.

As a synthetic continuity exercise, a receiver nominally generates 2 million complex samples per second. A verified hardware-counter discontinuity of 10,000 acquisition indices represents 5 ms of missing nominal sample time if the counter semantics and rate remained valid. If an exported file conceals that gap, a later 50 ms burst may appear five milliseconds earlier relative to

Copyright 2026, James M. Atkinson

subsequent records. An analyst should not fill the missing samples with zeros and then describe the added zeros as measured silence. A derivative file may use placeholders for computational convenience, but the validity mask, original byte digest and transformation record must make their status unmistakable. If the hardware-counter interpretation is uncertain, the gap duration must be reported conditionally rather than asserted as a measured fact.

A robust chain of custody maintains separate digests for the original sample object, the appropriate manifest and the custody ledger or signed event history. It identifies the algorithm used for each digest, the custodian, the acquisition device and the point in time at which the trusted reference digest was created. A successful later hash comparison supports byte continuity relative to that reference; it does not prove that the receiver was calibrated, that the acquisition was lawful, or that the clock was correct. Preserve minimally necessary original records under applicable access controls, and document any decimation, compression, filtering or redaction as an explicit derivative. A complete evidential package allows a sceptical reviewer to reconstruct the processing while still respecting the authorised limits of collection and disclosure.

Copyright 2026, James M. Atkinson

15.25 Continuity proofs for sampled RF records, missing-data masks and sustained throughput

A digital RF recording should be interpreted as a time-indexed sequence of actual acquisitions, not a file whose nominal size happens to equal an expected number of bytes. The physical sample count, sample aperture timing, sample format and declared validity must be connected. Buffered acquisition can overwrite records, duplicate blocks, reorder network packets or insert placeholder values while a downstream writer still produces a syntactically valid binary file. A cryptographic digest proves that the retained bytes have not changed since a specified digest was computed; it does not show that those bytes represent continuous samples acquired without loss. Forensic reproducibility therefore requires both data integrity and acquisition-state evidence, including sample counters and buffer-overrun records where the hardware exposes them.

The throughput budget is a necessary design calculation. Let f_s be complex samples per second, n_b be total stored bits per complex sample including both components, and R be the continuous payload rate in bytes per second. Then $R = f_s n_b/8$. For a complex stream of 50 million samples per second represented by two 16-bit signed integers, $n_b = 32$ bits per complex sample and the payload rate is 200 million bytes per second, approximately 190.7 MiB/s. For eight such independent streams, aggregate payload alone reaches 1.6 GB/s. Metadata, file-system overhead, buffering, concurrent readers, thermal throttling and occasional storage pauses add additional demands. A disk briefly achieving the nominal aggregate throughput in a synthetic benchmark has not proved that it can sustain acquisition for a full

Copyright 2026, James M. Atkinson

operational interval, especially while an analysis process competes for input/output resources.

A defensible continuity protocol uses monotonically increasing hardware or driver sample counters that identify any gaps between accepted blocks. For every acquisition transition record the commanded state, actual sample rate, time-reference state and whether any samples were discarded during filter settling or buffer resets. If the acquisition lacks a trustworthy sample counter, record that limitation and use independent hardware reference events where feasible; software file timestamps are not equivalent to sample-aperture timestamps. Clock drift requires a separately characterised mapping from index to physical time, and a step discontinuity should split the record into state intervals. Inserting zeros into a gap may be a useful explicitly labelled processing choice, but the zeros are synthetic values rather than observations of zero input energy.

A hypothetical continuity check illustrates the distinction. A recorder asserts an effective complex sample rate of 20 MS/s over a nominal 30-second interval, so 600 million complex sample positions are expected if that rate and interval are valid. Suppose hardware counters identify a missing span of 100,000 positions. The lost duration is 100,000 divided by 20 million, or 5 ms. A file whose application has filled that span with zeros may retain the expected byte length, yet actual observation covers only 29.995 seconds under the stated time mapping. A burst wholly inside the five-millisecond gap remains unobserved. An uncertainty statement about burst detection must preserve that gap rather than converting storage completeness into physical coverage.

Copyright 2026, James M. Atkinson

A portable metadata representation such as SigMF can document sample format, sample rate, acquisition context and capture boundaries. It should be treated as a metadata schema rather than a guarantee of scientific accuracy or comprehensive chain of custody. The laboratory may need extensions or companion records for sample-counter gaps, calibration, clock holdover, equipment serials, legal minimisation controls, digest lineage and software transformations. Preserve a manifest connecting original sample files to their metadata, segment validity maps and later derived spectra. If a corrected file is made, preserve the original and document the script version, parameters, input digests, output digests and rejected or censored intervals. Hashing the output without retaining those elements does not demonstrate how the result was produced.

Triggering introduces additional non-observation intervals. Pretrigger buffers may silently wrap before a candidate event is recognised, trigger comparators may have latency and hysteresis, and acquisition systems may rearm after a finite dead time. The trigger threshold must therefore be validated against weak and short reference events under the receiver's actual gain and filter state. A claimed five-second recording interval after a trigger may contain a shorter valid pre-event history than its user interface suggests. Acquisition testing should include controlled bursts placed near buffer boundaries and saturation recovery periods, with a separate reference clock or known event source to examine alignment. The final evidential report states the temporal and spectral support of the samples actually retained, not merely the duration printed in a filename.

Copyright 2026, James M. Atkinson

15.26 Additional study: sample continuity, acquisition clocks and the difference between stored bytes and observed RF time

A recorder that writes a syntactically valid file has not necessarily captured a continuous RF interval. Between the analogue-to-digital converter and persistent storage, samples may traverse FPGA buffers, DMA transfers, device-driver queues, network links, operating-system caches and user-space applications. At each boundary, an overload or backpressure condition can discard, repeat or reorder observations while preserving the appearance of a smoothly increasing file offset. A forensic description of recorded RF must therefore prove which physical sample instants correspond to each stored representation, or explicitly identify the intervals for which that correspondence is unknown. A checksum can certify that bytes have not changed after the checksum was computed; it cannot establish that the acquisition hardware sampled the expected physical waveform in the first place.

Let f_s denote the realised sample rate in complex samples per second and n an integer sample counter tied to acquisition hardware. Under constant-rate operation with a declared epoch t_0, ideal sample times satisfy $t_n = t_0 + n/f_s$. This relation is meaningful only while the counter represents actual ADC apertures and the rate is applicable. A host-generated file index or displayed timestamp cannot substitute automatically for a hardware count if samples can be omitted before the host receives them. When the clock changes or is disciplined, the time law may require a piecewise mapping or a measured phase/time correction. An abrupt rate change should create a

Copyright 2026, James M. Atkinson

new configuration interval in the evidence record, not a silent reinterpretation of all older samples using the latest nominal rate.

The data-rate calculation is a necessary but insufficient feasibility check. If each complex sample contains b_I bits for the in-phase component and b_Q bits for the quadrature component, the nominal uncompressed payload rate is $R_{bits} = f_s(b_I+b_Q)$. With the common symmetric case $b_I=b_Q=b$, the rate is $2bf_s$ bits per second. This is the rate of packed useful samples, before framing, timestamps, headers, transport overhead, storage allocation and error-correction or retransmission. A sample stream with sixteen-bit I and Q components at 100 million complex samples per second carries 3.2 gigabits per second, or 400 million payload bytes per second. A ten-minute uninterrupted capture would therefore require 240 gigabytes of payload under decimal units, before overhead. The calculation assumes the full stream is retained and that no channel decimation or compression changes the representation.

Peak write capability must be distinguished from sustained recording capability. An SSD benchmark showing a short-lived throughput above 400 MB/s does not establish that a specific computer, file system and temperature state can sustain the required rate over ten minutes. Internal garbage collection, wear management, background tasks, thermal throttling, encryption overhead and file-rotation behaviour can create pauses. Buffering can conceal a temporary write shortfall but cannot eliminate an indefinite rate mismatch. A useful acceptance test deliberately extends beyond the expected longest acquisition interval, monitors actual buffer occupancy and hardware lost-sample counters, and repeats under realistic computational and environmental loading. Successful copying of an

Copyright 2026, James M. Atkinson

existing file at high speed is not equivalent to simultaneous sampling, processing and writing from the receiver chain.

For a finite queue with capacity C bytes, incoming rate R_in and service rate R_out, the simplest fluid approximation while nonempty is dQ/dt = R_in−R_out, where Q is bytes and rates are bytes per second. If R_in exceeds R_out by constant positive ΔR, a previously empty queue fills in time C/ΔR. That time is a bound only for the stipulated deterministic rates; real storage systems have variable service and burst traffic. A correct engineering design needs a margin for the distribution of service interruptions and for the maximum input burst, not merely equality of average rates. When a queue saturates, the acquisition architecture must specify whether it discards oldest samples, newest samples, whole packets or simply blocks upstream flow. Each policy creates a different evidential gap and must be included in the file's continuity metadata.

A deliberately synthetic calculation assumes a 400 MB/s payload stream, 32 GB of free buffering and a sustained storage service rate of 360 MB/s. The deficit is 40 MB/s, so even the initially empty buffer fills after 32,000 MB divided by 40 MB/s, or 800 seconds, about 13 minutes and 20 seconds, ignoring all overhead. A 20-minute recording cannot be made continuous by that buffer under the stipulated constant rates. Increasing the buffer to 64 GB delays failure but does not resolve the negative long-term throughput margin. The correct architectural remedy is to increase sustained service rate, reduce stored throughput through valid acquisition changes, or formally limit recording duration, rather than treating the transient benchmark peak as proof of an unlimited capture.

Copyright 2026, James M. Atkinson

The loss record should distinguish three levels of certainty. A hardware counter discontinuity can establish that sample indices are absent; a validated frame sequence may reveal packet loss after acquisition; and a processing check can establish that a derived file omitted samples despite their presence in the native record. Each observation supports a different reconstruction question. A file with no detectable counter gaps may still contain overwritten samples if the device counter itself was reset, duplicated or not exposed. Two identical waveform buffers do not prove duplication when a truly periodic source could produce equal samples, but repeated buffers with identical hardware sequence identifiers and incompatible timestamps are strong evidence of a transport or software fault. The reviewer should examine both numerical content and acquisition metadata before drawing a conclusion.

A recording gap must remain a gap in subsequent time-frequency analysis. Concatenating two surviving buffers and assigning consecutive nominal times compresses the physical timeline, potentially converting two separate bursts into an apparent longer event or shifting the phase of an oscillator. Zero-padding preserves index positions and can be appropriate for some displays, but the inserted zeros are not measurements of zero incident voltage. Interpolation can support an explicitly model-dependent estimate, yet it does not restore directly observed RF data and may be especially unreliable around a transient or changing receiver state. For evidential purposes, the missing-sample mask should be retained alongside any repaired derivative and carried through every analysis that depends on timing or phase.

Copyright 2026, James M. Atkinson

A second hypothetical example considers a missing segment of 24,000 complex samples at an actual sampling rate of 48 million samples per second. The physical gap is 24,000/48,000,000 = 0.0005 seconds, or 0.5 ms. At a carrier-offset frequency of 20 kHz in complex baseband, the unobserved phase evolution across that interval is 2π times 20,000 times 0.0005 = 20π radians, ten full cycles. Its modulo-2π endpoint phase appears unchanged under the stipulated constant-frequency model, but that equality does not prove signal continuity or exclude a transient within the gap. A different unknown frequency excursion could add additional phase. A coherent phase estimate crossing the gap must disclose reliance on the assumed frequency model and the uncertainty of the missing interval.

A third example concerns random loss versus systematic gaps. If a recorder drops exactly one buffer at every file rollover, repeated test runs may show excellent average throughput while leaving a periodic observation blind spot. The lost samples are not independent random events. A probability-of-capture calculation that multiplies an assumed per-buffer survival rate across repeated sweeps would be invalid without evidence for that model. A source whose bursts are synchronised to file rollover could repeatedly coincide with the gap, creating systematic nondetection. A qualification test should therefore vary event start phase against rollover, queue flushes, gain transitions and other recurring operational cycles.

Copyright 2026, James M. Atkinson

15.27 Evidence-grade metadata and reproducible processing

A portable complex-sample representation requires more than an extension identifying the file as I/Q data. The metadata should state sample type, endianness, number of bits, actual sample rate, applicable centre frequency, acquisition epoch, sample-offset conventions, capture segments, device identity and consequential settings. The SigMF project provides an openly documented metadata approach for signal recordings, but a correctly formatted metadata document is only as reliable as the underlying observations that supplied its fields. A false timestamp or stale gain state remains false when encoded in valid JSON. The recorder must tie metadata to actual device status and calibration evidence, and note where such evidence is unavailable.

Data provenance has a sequence. First preserve the earliest useful native representation and its acquisition-state record, preferably with a contemporaneous integrity digest and restricted write access. Next produce a derivative for analysis without replacing the original. Record the processing code version, parameter values, selected intervals, calibration files, missing-data masks and any changes in time or frequency coordinates. Finally retain the scientific finding separately from the derived plot or classifier output. A cryptographic hash proves equality to the bytes hashed, not authenticity of the originating RF event, correctness of the receiver clock, or legal authority for the acquisition. These distinctions prevent a sophisticated chain-of-custody mechanism from being asked to support a proposition it cannot logically establish.

Copyright 2026, James M. Atkinson

A fourth constructed example uses a sixteen-channel architecture, each retaining a 2 MHz complex stream with sixteen-bit I and sixteen-bit Q. The total payload rate is 16×2,000,000×4 bytes/s = 128 MB/s. A forty-five-minute acquisition carries 345.6 GB of payload before metadata and storage overhead. If a nominal 512 GB volume has only 300 GB actually available and no channel is reduced, the recording cannot hold the complete requested duration. A software status that displays available disk capacity in gibibytes should not be directly compared with decimal gigabytes without conversion. The design must calculate actual free bytes, reserved space and validated sustainable write capacity rather than rely on the drive's advertised nominal size.

A fifth synthetic example illustrates timestamp ambiguity. Two streams show event marks separated by 1.0 ms. The first timestamp is established as the ADC sample aperture with ±10 μs uncertainty; the second is a host file-write time with variable latency between 0.2 and 2.0 ms. Without a measured second-stream latency, the apparent millisecond separation cannot be interpreted as a source propagation delay or precise simultaneity. The second mark may refer to a different physical instant entirely. Calibrating the storage or transport path can narrow that uncertainty, but a common wall-clock display by itself cannot do so. Any triangulation or coherent array claim based on such times would exceed the supported evidence.

The final acceptance requires an end-to-end known-event test. Inject an authorised, time-labelled RF test pattern while simultaneously monitoring hardware counters, buffers, device status, derived file indices and persistent storage. Include test events before and after deliberate file rollover, high

Copyright 2026, James M. Atkinson

disk load, gain changes, receiver restart and temporary network impairment. Compare the independently known event schedule with the retained native record. Record failed and partial captures, not solely successful files. The release dossier should provide the set of physically observed intervals, the missing-sample masks, validated rate and time mappings, and the exact storage representation. Only then can an analyst responsibly describe a captured interval as continuous within the stated uncertainty and operating conditions.

Copyright 2026, James M. Atkinson

15.28 Advanced technical expansion. Continuity proofs for burst-triggered I/Q evidence

A digital file can be internally well formed while failing to represent continuous acquisition of the intended RF channel. The distinction between sample indexing, physical aperture time, trigger time, buffering, transport and storage must therefore be maintained in the recording model. Let a converter sample at a realised rate f_s in complex samples per second and let each retained complex sample occupy b bytes in the selected format. The uncompacted minimum payload rate is $R = f_s b$ bytes per second, before packet headers, metadata, file-system overhead or redundancy. For a hypothetical single complex channel at 20 million samples per second stored as two 16-bit signed integers, b = 4 and the raw payload rate is 80 MB/s in decimal units. Eight such channels need 640 MB/s, or approximately 2.304 TB per hour, before storage overhead. These are capacity-planning results; they do not prove that a particular host or disk can sustain the rate without lost data.

A trigger introduces a second time base. The threshold crossing occurs at some physical or digital decision stage; the software notification and file-write start may occur later. If the desired report needs the first microseconds of a brief pulse, a pretrigger buffer must contain valid samples acquired before the trigger and must retain their sample indexes. A buffer of L complex samples at sample rate f_s contains L/f_s seconds of nominal pretrigger history. For example, 262,144 samples at 20 MS/s represent approximately 13.1072 ms. That figure is not an independent guarantee that the buffer was correctly aligned with the event or that the

Copyright 2026, James M. Atkinson

earliest samples survived subsequent backpressure. Verification requires a known reference with an independently marked onset and a record of the trigger-comparator and sample-counter relationship.

Missing or repeated buffers can be particularly treacherous because an application may export a file with the expected number of samples after inserting, omitting or reordering data. A file-length check alone does not establish acquisition continuity. Use monotonic hardware sample counters or another independently validated continuity mechanism, link transport sequence numbers to original acquisition indexes where available, and record discontinuities as explicit gaps rather than silently concatenating the fragments. A checksum proves the exported bytes have not changed since a specified reference; it does not prove that the bytes were a complete representation of the earlier analogue event. Similarly, an unchanged timestamp written by software may reflect a reconstructed clock rather than each actual sample aperture. The provenance record should distinguish measured hardware time from derived time.

Recording performance should be tested under the worst credible sustained workload, not only by copying a previously captured file. Real-time acquisition involves interface transfer, buffers, operating-system scheduling, metadata production and storage flush behaviour that do not appear in a synthetic disk write benchmark. Test with the intended sample format, channel count and maximum recording duration, while independently monitoring source identity and sample continuity. Include cases where the processor is busy, the storage subsystem approaches full capacity, a device changes gain or preselector state, and a network link experiences bounded delay. Preserve every failure and the exact condition that produced it. A

Copyright 2026, James M. Atkinson

successful ten-second recording cannot by itself establish uninterrupted eight-hour operation, especially when thermals and write amplification change over time.

SigMF provides a concrete public metadata framework for linking sample files with descriptions of format, sample rate, captures and annotations. It does not replace the investigator's legal authority, calibration records or proof of physical continuity. An acquisition package should include explicit complex-data type and endianness, declared and verified sample rate, time and frequency references, capture start indexes, channel identifiers, processing revisions and gap annotations. If the underlying format uses a global sample rate but the receiver changed rates during a recording, either partition into separate valid records or provide an explicitly supported representation that preserves each actual time basis. Misrepresenting mixed-rate data as one uniform sequence can corrupt every subsequent frequency and timing inference.

End-to-end assurance must also preserve transformed outputs without confusing them with original measurements. Retain the raw I/Q stream where authorised, a cryptographic digest, a manifest linking auxiliary metadata and recorded files, the immutable configuration-state ledger and separate analysis products. Each derived waterfall or decoded feature should identify its input ranges, algorithm, coefficients and numerical environment sufficiently for independent reproduction. A scientifically useful retention policy may preserve technical subsets rather than unrelated communication content, but the minimisation decision and its consequences for possible reanalysis must be stated. An absent sample or

Copyright 2026, James M. Atkinson

discarded band remains absent, regardless of how carefully the surviving bytes are signed or archived.

Copyright 2026, James M. Atkinson

15.29 Event-driven capture without treating quiet intervals as proof that no emission existed

A massively parallel receiver should not be forced to choose between archiving every byte for four hours and storing only attractive events displayed by one detector. Full-rate continuous spectral analysis is a computational service, whereas full-rate raw I/Q retention is a separate storage policy. A rational architecture runs both a fast event detector and a narrowband spectral estimator from the same calibrated acquisition path, with a rolling pretrigger buffer in each frequency slice. Candidate events cause selected intervals to be retained at the finest available representation needed for the task, while the system continuously records coverage status, detector configuration, valid-gain state, overload flags and sample continuity across every band. That arrangement can reduce the long-term volume greatly, but it cannot guarantee retention of emissions which all active detectors miss. Its assurance must be defined empirically for stipulated event classes.

The front-end FPGA should attach a monotone sample counter to blocks before sending them to host software or GPU memory. The block manifest includes channel identity, sample-rate epoch, RF tuning, calibration identifier, gain and preselection state, reference-clock lock, packet serial, first and last sample indices, and checksum or authenticated digest as appropriate. If consecutive received blocks have noncontiguous counters, the storage record contains an explicit hole, even if the application writes a file that appears continuous. Placeholder zero samples can help preserve time axes for some processing, but they must be distinguished from actual

Copyright 2026, James M. Atkinson

acquired zeros. Decimation and channelisation outputs retain the source block range and filter group delay. The original ADC-derived I/Q, when preserved, must not be silently replaced by a corrected or denoised copy.

A multi-resolution detection cascade begins with coarse wideband power, impulsive change measures, and narrow frequency-cell statistics appropriate to their respective waveform families. A fast detector may inspect overlapping short windows to preserve microsecond transients; a slow estimator may integrate tens of milliseconds to resolve a persistent carrier near the 30 Hz RBW requirement. A trigger can be raised by energy, cyclostationary structure, matched-filter correlation against an authorised test waveform, or a validated machine-learning anomaly score. These triggers have different observation domains. A threshold calibrated with isolated tones cannot automatically detect chirped pulses, frequency-hopping events or emissions adjacent to a large blocker. Fusing their scores requires explicit dependence and false-alarm modelling, not treating four correlated triggers as four independent confirmations.

Event windows must be sized relative to trigger latency and instrument recovery. If the detector recognises a burst after L seconds and the rolling buffer holds B seconds before the current write index, retaining the complete burst leading edge requires adequate B relative to L plus any additional pipeline and classification delay, with uncertainty and queueing variation. A nominal ten-millisecond ring buffer can lose a short event if trigger decisions are delayed longer by a GPU queue, a storage flush or an expensive classifier. Backpressure therefore requires active monitoring, admission control and a priority path that can preserve the earliest candidate samples. A report should state when the recorder continued

Copyright 2026, James M. Atkinson

collecting but could not persist triggered data, rather than presenting the missing event as undetected by the RF channel.

Avoiding so-called dead-air recording must not erase the statistical denominator of a negative finding. A system can preserve lightweight background summaries with timestamps, spectral-noise estimates, threshold versions, coverage masks, observed dropouts and periodic random challenge snippets. A small prespecified fraction of noise-only raw windows can be retained as an audit sample, where authorised, so that an independent examiner can test whether the event detector had become biased by adaptive baselines or unexpectedly structured interference. Unselected intervals may contain below-threshold transmissions. They are properly called unretained, not demonstrated empty. An operator who silently removes them from the history cannot later calculate probability of missed events or explain why no I/Q was saved in a relevant band.

Signal-identification products are a directed acyclic graph of derivatives linked to original samples. A detected event receives a unique identifier, one or more source chunk hashes and exact source sample intervals. Processing nodes may generate a narrow I/Q extraction, a carrier offset estimate, a constellation or modulation feature, a spectrogram, a pulse interval list or legally authorised content recovery. Each derived item retains its processing version, filter passband, time mapping and classification uncertainty. A spectral line which survives a change of software cannot be claimed independent corroboration when both outputs derive from the same raw buffer. The appropriate challenge uses a sufficiently independent measurement path or explicitly acknowledges shared-error structure.

Copyright 2026, James M. Atkinson

Validation should include blind inserted events in noise-only stretches, weak pulses of unknown starting phase, frequency-agile emissions crossing slice boundaries, overlapping waveforms, and strong blockers which stress gain and digitiser headroom. Predeclare event-detection and extraction acceptance criteria by waveform class, frequency region, level, duration and operating state. Record both successes and misses. A four-hour observation should be represented by a time-frequency coverage grid and a separate event ledger; the absence of a saved raw file in a grid cell is not itself proof of signal absence. Storage savings, lawful minimisation and evidential integrity are compatible only when the decision to retain or discard samples remains reconstructable and bounded by a disclosed detector capability.

Copyright 2026, James M. Atkinson

15.30 Massive I/Q ingestion, GPU scheduling and four-hour storage accounting

Forty gigahertz of genuinely simultaneous useful RF passband is a federation of receiver front ends, converters, frequency translations and channelisers unless a particular instrument independently proves direct acquisition at the required aggregate throughput. The term aggregate is essential. If four hundred nominal hundred-megahertz complex slices cover adjacent, nonoverlapping bands, the ideal complex sample rate totals forty billion samples per second. Practical spectral guard regions, filter transition bands and duplicated overlap must be added if the required useful coverage is still forty gigahertz. Each slice must have a well-defined centre frequency, sign convention and calibrated overlap correction. A stitched 40 GHz heat map assembled from disjoint times does not satisfy the instantaneous requirement, no matter how smooth it looks.

At an ideal forty billion complex samples per second, sixteen-bit I and sixteen-bit Q ingest at 160 decimal GB/s. A 100 millisecond rolling buffer across all slices requires 16 GB of payload in this representation. One second requires 160 GB and thirty seconds 4.8 TB, before headers or replication. The resources can be distributed among receiver nodes with local memory rather than forced into one GPU, but the total cannot be wished away by choosing a smaller FFT bin. A packed fourteen-bit stream requires 140 GB/s of ideal source payload; if each complex pair is padded into two sixteen-bit words before transmission, it requires 160 GB/s on that path. A twenty-four-bit representation requires 240 GB/s and more than 3

Copyright 2026, James M. Atkinson

PB if continuously archived for four hours. The source converter's effective number of bits does not improve simply because the storage type is wider.

NVIDIA's cuFFT supplies planned GPU transforms and batched execution, while GPUDirect RDMA can reduce unnecessary host-memory movement on supported device topologies. Neither creates a performance guarantee for an unspecified video card. The system must benchmark achievable sustained samples per second after including frequency translation, channel filters, overlapping FFT windows, scaling, trigger classification, source-to-buffer transfer, event copying, metadata and durable storage. The CPU, FPGA, GPU, NIC and NVMe stages require queue-occupancy and missed-deadline counters. Fixed FFT plan buffers and well-designed asynchronous streams can improve predictability, but shared accelerator memory bandwidth or simultaneous storage traffic may still become the limiting resource.

The fine-resolution branch is particularly expensive if all spectral bins are emitted continuously. Forty gigahertz divided by thirty hertz is approximately 1.333 billion nominal frequency cells. A single four-byte float per cell occupies about 5.333 GB for one complete-resolution spectral image. Twenty such full images per second would constitute about 106.7 GB/s of output, even before metadata or multiple detector estimates. Therefore the spectral engine should create hierarchical products: coarse continuously updated occupancy, targeted fine-resolution bins, sparse peak tables, selected narrowband complex extracts, and independently sampled quality-control tiles. If every full fine-resolution image is still required, the budget must include its output rate just as rigorously as the ADC input rate.

Copyright 2026, James M. Atkinson

An FFT calculation is not free merely because the raw IQ was not written to disk.

The observation duration of four hours places a separate demand upon system health. Verify that oscillators remain in qualified states, memory and disk pools do not exhaust, GPU temperatures do not cause unrecorded throttling, and all receiver slices remain aligned. Run controlled known-signal challenges at predeclared intervals without contaminating unrelated survey evidence, and mark calibration-pulse intervals in metadata. Accumulate per-slice coverage, invalid-state time, event retention volume, dropped-block counts and monitoring interruptions. The final report should give these measures alongside detected signals; it should not describe the intended four-hour programme as four hours of valid simultaneous observation if some slices were unavailable or uncalibrated.

Copyright 2026, James M. Atkinson

15.31 Archiving policies for fifteen minutes to seventy-two hours of instantaneous forty-gigahertz observation

A receiving installation can claim continuous observation over a specified duration only when its acquisition paths, timestamps, gain states and processing validity remain sufficiently documented throughout that interval. The length of the requested observation is not a cosmetic report field. Fifteen minutes may expose the response to a controlled short laboratory stimulus; sixty minutes may cover several cycles of a periodic building system; four hours may span shifts in local radio occupancy; eight or twelve hours may reveal daypart-related activity; twenty-four and thirty hours may disclose one complete daily pattern plus transition behaviour; and seventy-two hours may expose variations across successive working periods. These are possibilities to test, not reasons to assume that an unobserved transmitter must reveal itself eventually. A three-day observation with a blind frequency region can provide weaker evidence about that region than a ten-minute correctly configured test. The aim of this section is to separate time coverage, spectral detail, preserved waveform content and conclusions defensible from each record.

Adopt the author's system requirement of forty gigahertz of instantaneous aggregate useful receiver bandwidth, continuously analysed by distributed GPU-enabled SDR nodes. Let B denote the summed complex-sampled useful bandwidth, set nominally to 40,000,000,000 hertz, and let R_c denote the corresponding ideal aggregate complex sample rate in sample pairs per second. For a collection of independent complex slices whose usable widths sum to B, the ideal one-sample-per-hertz complex representation has R_c

Copyright 2026, James M. Atkinson

approximately equal to B. This is an accounting simplification: oversampling, nonrectangular anti-alias transition bands, overlapping receiver slices and duplicated recording may require a higher actual aggregate data rate. It is not a claim that one commercially specified converter samples a contiguous forty-gigahertz band, nor a claim that usable sensitivity or a four-decibel noise figure holds at every frequency. Each receiver lane must be independently calibrated for its selected preselector, analogue conversion, clock and reference plane.

If b is the stored number of bits for EACH I and Q component, an ideal packed complex pair contains 2b bits. The payload rate R_bytes in bytes per second is R_c times 2b divided by 8. Over an observation of T seconds, uncompressed data volume V_bytes equals R_bytes times T. Both expressions are exact under the stated packed, continuous-sample accounting. Decimal gigabytes and petabytes mean 10^9 and 10^15 bytes, respectively. This avoids the often unnoticed factor-of-two error in calculations that count only I, and the factor-of-eight error in calculations that confuse bits and bytes. It also prevents a 24-bit output container from being described as 24-bit analogue resolution. The acquisition equipment must separately demonstrate actual useful ENOB, bandwidth, signal handling and sample continuity.

The reference cases used here are 8-, 12-, 14-, 16- and 24-bit representations for each component. Their ideal packed payload rates are respectively 80, 120, 140, 160 and 240 decimal gigabytes per second. Real data interfaces frequently pad twelve- and fourteen-bit signed samples to sixteen-bit words, producing the same sixteen-bit transport budget even though the ADC provides fewer nominal bits. Some systems represent twenty-four-bit values

Copyright 2026, James M. Atkinson

as thirty-two-bit integers or floating-point words, which similarly increases traffic to 320 decimal gigabytes per second. No storage model should claim the packed saving until the device output, direct-memory-access descriptors, driver, GPU input and archived on-disk format have all been shown to retain the shorter representation. Conversion on ingestion can enlarge the live memory footprint even when the eventual archive is packed.

At fifteen minutes, the requested observation spans 900 seconds; at sixty minutes, 3,600 seconds; at four hours, 14,400 seconds; at eight hours, 28,800 seconds; at twelve hours, 43,200 seconds; at twenty-four hours, 86,400 seconds; at thirty hours, 108,000 seconds; and at seventy-two hours, 259,200 seconds. Each interval is a separate acceptance case, with the acquisition-state ledger required to establish that the receiver was actually observing during that interval rather than merely remaining powered on. A timestamp on a file written after an interruption does not bridge the missing interval, and a checksum on an internally consistent partial file cannot recover samples that never reached the host.

The following complete uncompressed payload matrix is calculated at nominal R_c = 40 billion complex sample pairs per second, using tightly packed I and Q components. For fifteen minutes, the volumes for 8, 12, 14, 16 and 24 bits per component are respectively 0.072, 0.108, 0.126, 0.144 and 0.216 decimal petabytes. For sixty minutes they are 0.288, 0.432, 0.504, 0.576 and 0.864 petabytes. For four hours they are 1.152, 1.728, 2.016, 2.304 and 3.456 petabytes. For eight hours they are 2.304, 3.456, 4.032, 4.608 and 6.912 petabytes. For twelve hours they are 3.456, 5.184, 6.048, 6.912 and 10.368 petabytes. The duration scaling is linear because this example holds aggregate sample rate, precision, and recording duty fraction fixed.

Copyright 2026, James M. Atkinson

For twenty-four hours, the same ordered 8-, 12-, 14-, 16- and 24-bit volumes become 6.912, 10.368, 12.096, 13.824 and 20.736 petabytes. For thirty hours they become 8.640, 12.960, 15.120, 17.280 and 25.920 petabytes. For seventy-two hours they become 20.736, 31.104, 36.288, 41.472 and 62.208 petabytes. These values exclude equipment redundancy, filesystem protection, transport encapsulation, storage parity, reanalysis duplicates, logging, receiver-band overlap and uncompressed temporary GPU representations. Their purpose is to define the size of the problem before a product proposal says that the network will simply record all I/Q. A four-hour 16-bit archive is over two petabytes of ideal payload, and a seventy-two-hour archive of the same kind is over forty-one petabytes. Neither figure is a measured system performance result.

The word archive must be qualified by representation. A continuous low-rate occupancy journal can cover the full observation duration while storing only per-band calibration state, selected power statistics and sparse event descriptors. A continuous frequency-time spectral archive can retain high-resolution channel energies, averaged and maximum statistics, occupancy masks, local noise estimates and validity flags, but generally cannot reconstruct the original complex waveform after magnitude formation. A triggered raw-I/Q archive can retain full complex samples in selected frequency-time windows, provided its trigger, ring buffer and export channel actually preserve the relevant precursor and end of the event. Finally, a full-rate raw-I/Q archive preserves the original data representation continuously but requires the extreme throughputs calculated above. These four categories must never be conflated in promotional language or in an evidential report.

Copyright 2026, James M. Atkinson

At thirty-hertz nominal bin spacing, forty gigahertz spans about 1.333 billion frequency bins across the distributed receiver slices. A hypothetical single snapshot storing one unsigned sixteen-bit scalar per frequency bin therefore contains about 2.667 decimal gigabytes before timestamps, uncertainty or state metadata. If such full-frequency snapshots are archived once per second for seventy-two hours, the ideal store would contain 691.2 decimal terabytes. If they are archived once every ten seconds, it falls to 69.12 terabytes, but transient persistence within those ten-second intervals cannot be reconstructed from the decimated records. More aggressive quantisation or hierarchical aggregation can reduce this volume further only by surrendering information and documenting exactly which statistics survive. Bin spacing alone does not establish a thirty-hertz equivalent noise bandwidth: the actual window ENBW and overlap processing must also be specified.

Thirty-hertz spectral resolution does not demand a thirty-hertz ADC, nor does it grant thirty-hertz time resolution. The transform input must retain enough observation time for the selected FFT window, and the continuous receiver must simultaneously preserve the fast transient path for pulses whose duration is much shorter than one over thirty seconds. For a fixed complex sample rate f_s per channel and an N-point transform, the nominal spacing is f_s divided by N hertz; the effective noise bandwidth depends upon the selected window and its squared weight. Nonoverlapped thirty-hertz frames cannot describe exactly when a microsecond pulse occurred, even if energy from the pulse influences some of the resulting bins. Use a parallel wideband short-window event detector, a narrow high-resolution

Copyright 2026, James M. Atkinson

spectral estimator and a rolling pretrigger waveform buffer, each with an explicit purpose and compatible sample index lineage.

The storage-saving proposition is not to stop observing empty space. It is to stop routinely retaining the most expensive raw representation whenever the authorised measurement objective permits a less informative summary. The full receiver must still monitor all nominal frequency slices throughout the chosen fifteen-minute to seventy-two-hour interval. For each valid slice, record the start and end sample counters, actual sample rate, receiver gain, frequency reference, reference-clock lock, FFT and detector settings, overload condition, packet-loss information, dynamic threshold state and whether the event-preservation pathway was available. A discarded raw interval should be recorded as observed but not waveform-retained only if the corresponding monitoring capability and data quality were demonstrated. A detector failing to identify a low-power or unmodelled signal does not create proof that no signal was present.

Define a retained-bandwidth-time fraction q as the sum over stored event segments of their useful archived bandwidth multiplied by their retained duration, divided by the product of forty gigahertz and the total observation duration. This dimensionless quantity is helpful for first-order payload budgeting only if event segments are nonoverlapping in their underlying source sample intervals and stored at a common precision. Real systems often retain overlapping pretrigger intervals, adjacent filter-guard regions, multiple signal representations or repeated exports, so the actual byte ledger is authoritative. At sixteen bits per I or Q component and a nominal q of 0.1 percent, average retained raw payload would be 160 megabytes per second, equal to approximately 2.304 terabytes over four hours or 41.472

Copyright 2026, James M. Atkinson

terabytes over seventy-two hours. At q of one percent, those figures rise tenfold. Those are illustrative duty fractions, not forecasts of actual RF occupancy; an installation surrounded by strong transmitters may spend much longer in triggered preservation.

The retention fraction must never be used to size the shortest-term buffers. A dense simultaneous burst across all monitored bands could require the raw input path to accept the full 80 to 240 gigabytes per second, even if long-term average retention is one-thousandth of that rate. A resilient architecture puts independent, bounded ring buffers near each acquisition node, assigns fast local triggering responsibility to FPGA or host logic, and moves candidate segments to slower durable storage asynchronously. Every transition between memory, GPU and disk has an explicit queue-depth limit and overflow policy. At nominal sixteen-bit complex precision, a five-second pretrigger archive for a one-gigahertz complex slice requires twenty decimal gigabytes before overhead. Forty such slices would need eight hundred gigabytes if the same five-second history were retained simultaneously across the full forty gigahertz. The system must demonstrate that its memory can sustain worst-case concurrent events rather than relying on average occupancy estimates.

For fifteen minutes, a laboratory acceptance exercise can afford intensive whole-band spectral records, short raw buffers and repeated controlled reference injections while testing the most demanding queue and clock transitions. At sixty minutes, stable source operating conditions are more important: periodic gain calibration, rotating file segments, counter rollover, device temperature and GPU scheduler behaviour should be tested without disabling acquisition. A four-hour trial should deliberately include

Copyright 2026, James M. Atkinson

simultaneous event arrivals in several frequency slices, and should verify sustained disk flushing as well as the return of the buffers to their designated free-space watermark. In each case, test no-event intervals with a known weak injected event to determine whether the classifier may be silently missing the very waveform category for which a negative report is contemplated.

At eight and twelve hours, inspect oscillator holdover, synchronisation sources, sustained thermal load and the complete distribution of queue latencies rather than merely their average. A narrow ring-buffer margin that survives a quiet fifteen-minute test may fail during repeated bursts later in the observation. At twenty-four hours, assess day-night environmental drift, equipment-state changes and unintended daily patterns in the triggering threshold. The archive should retain a continuous coverage timeline so that a rise in reported event count can be separated from a gain adjustment or a changed spectral threshold. Daily summary records should be derived from retained raw events and validated spectral statistics, not from a user's manual notation of apparently quiet periods.

A thirty-hour run deliberately exceeds a conventional twenty-four-hour cycle and is useful for examining whether clock, thermal or signal-occupancy patterns repeat at different local times; the analyst must not infer stationarity from one repeated observation. A seventy-two-hour campaign raises problems of disk wear, transient backlog, reference-source changes, leap-second or time-scale representation, software revisions, and unattended failures. Design the experiment to include controlled loss-of-reference and dropped-packet tests that are marked explicitly rather than buried. Automated checkpointing should produce cryptographically

Copyright 2026, James M. Atkinson

verifiable manifests for completed recording epochs, and a restart should create a new provenance epoch linked to the preceding one, never a fictitious uninterrupted interval. Seven decades of forensic rhetoric cannot repair seven seconds of unrecorded source data.

The signal-extraction workflow operates on indexed candidates rather than blindly reprocessing the entire forty-gigahertz archive at full precision. Each candidate starts with an RF frequency interval, start and stop sample indices, receiver and clock identities, detector explanation, selection-threshold history and confidence or uncertainty statement. The extractor locates raw ring-buffer slices, retrieves the original packed representation, verifies sample continuity, converts to complex numerical coordinates with an explicitly documented scale, and selects a digital mixing and decimation path with appropriate anti-alias filtering. It then computes the permitted features: instantaneous frequency, amplitude and phase tracks, pulse-repetition pattern, modulation and code hypotheses, and spectral neighbourhood. Compare candidate features with independent reference recordings or held-out test conditions before declaring a waveform class. Do not treat a decoder's successful output as proof of source identity, physical location or legal authority to inspect carried content.

An event should retain its original complex samples plus a separate, reproducible chain of derived products. Record original sample number, original converter width, byte ordering, sign convention, physical centre frequency, acquisition rate, reference-clock condition, gain and analogue path, filter definitions, group-delay and decimation relationships, calibration dataset identifiers, processing-software digest, extracted signal classification and human examination. The metadata schema may follow the

Copyright 2026, James M. Atkinson

public Signal Metadata Format where appropriate, extended with clearly versioned private provenance fields. Such metadata describes a preserved record; it does not prove that the detector discovered every signal during unretained intervals. Encryption, retention periods and disclosure should be bounded by the lawful defensive purpose and the applicable jurisdiction.

The proper archival acceptance test is two-dimensional. First, establish whether the installation continuously observed the required forty gigahertz, including receiver overlap regions, clock lock, sample continuity, storage availability and successful coverage manifests, for each of the specified durations. Second, establish which event families, levels, widths, modulations and arrival times the detector preserves reliably, with known false-positive and false-negative characteristics under representative blockers and environmental changes. A system can satisfy coverage while missing a specified weak pulse because its trigger is insensitive; it can satisfy pulse detection in selected bands while failing forty-gigahertz continuity; and it can preserve raw events while mislabelling the waveform due to I/Q sign error. Publication-quality claims must report these possibilities separately, with quantitative results attributed to actual tests rather than projected storage arithmetic.

Chapter Summary

Receiver coverage depends on time as well as sensitivity. Trigger behavior, pretrigger context, sample continuity, metadata, and reproducible processing determine whether an intermittent event can support a durable technical conclusion.

Model 15A begins with usable acquisition intervals and a positive contiguous-overlap criterion. It derives eligible event starts, merges their periodic union and introduces a phase distribution only when justified. Uniform timing, independent repeated trials and known detector capability are separate premises. A phase-locked event can miss indefinitely, and disconnected fragments do not become one uninterrupted capture.

The trigger and recording paths can observe different representations of the same event. Test their relationship with controlled stimuli, including closely spaced events and required pretrigger context. Preserve state changes and the timing reference of the trigger. A successful isolated pulse does not establish recovery behavior, full-event capture or availability throughout a nominal dwell.

Record the actual sample encoding and sustained storage behavior. Counters, validity flags and gap records establish acquisition continuity; hashes establish later byte consistency. Bind derived results to native samples, corrections and processing parameters. Reconcile planned, commanded, valid and preserved coverage before reporting a negative result, retaining the event classes and intervals that were never tested.

Chapter 15 Assessments

This section contains 250 items: 100 multiple-choice, 100 fill-in-the-blank, 25 essay and 25 discussion. Choose one best answer for each multiple-choice item. Supply the requested technical term, quantity or condition for each blank. For essay and discussion responses, explain the governing mechanism, assumptions, evidence and limits of the claim. Numerical assessment cases use hypothetical inputs unless an item explicitly identifies a published source. Retain units and distinguish power, voltage and logarithmic quantities. Answers, rationales and response guidance follow the complete question set; their review links lead to the supporting text.

Multiple-Choice Questions

V011-C15-MCQ-001. What constitutes a qualifying capture in Model 15A?

A. One valid record supplies the specified positive contiguous overlap, with detector prerequisites satisfied

B. Several disconnected fragments have the same total duration

C. A tuning command was issued during the event

D. A trigger indicator illuminated regardless of sample validity

Answer: A. The criterion applies to one usable contiguous record and is conditional on detectability. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: One valid record supplies the specified positive contiguous overlap, with detector prerequisites satisfied.

Distinguishing consideration: compare this with option B, “Several disconnected fragments have the same total duration”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-002. For window [a,a+D] and event duration b, which eligible-start interval applies when $0<r\leq min(b,D)$?

A. [a+r−b,a+D−r]

B. [a−b,a+D]

C. [a+r,a+D+b−r]

D. [a,a+D+b]

Answer: A. The two ends enforce at least r contiguous overlap with the event.

Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: [a+r−b,a+D−r].

Distinguishing consideration: compare this with option B, "[a−b,a+D]"; that competing statement does not meet the question's stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-003. Why merge eligible-start intervals before finding capture probability?

A. Their lengths are always equal

B. The same event phase can qualify in more than one window

C. Every window is statistically independent by definition

D. The union makes detector sensitivity irrelevant

Answer: B. Union length counts each eligible phase once. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: The same event phase can qualify in more than one window.

Distinguishing consideration: compare this with option A, “Their lengths are always equal”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-MCQ-004. In Application 15A.1, why not obtain a point-event rule by setting r=0 in the non-strict overlap test?

A. Even disjoint intervals satisfy overlap at least zero

B. A point event must be captured in every window

C. The schedule period would become zero

D. A point event necessarily has infinite bandwidth

Answer: A. The separate rule requires the instant to fall inside a usable window.

Source: §15.4 Application 15A.1: Distinguish a point observation from full capture of a short event (p. 8685)

Why the selected alternative fits: Even disjoint intervals satisfy overlap at least zero.

Distinguishing consideration: compare this with option B, “A point event must be captured in every window”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.1: Distinguish a point observation from full capture of a short event.

Review: Chapter 15 — Application 15A.1: Distinguish a point observation from full capture of a short event.

V011-C15-MCQ-005. In Application 15A.7, what happens when a fixed-phase event repeatedly misses the same periodic window?

A. Its capture probability automatically approaches one with file count

B. It can miss indefinitely

C. Its phase becomes uniform after ten events

D. The receiver noise figure improves with repetition

Answer: B. A new independent phase experiment or changed schedule is needed.

Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

Why the selected alternative fits: It can miss indefinitely.

Distinguishing consideration: compare this with option A, “Its capture probability automatically approaches one with file count”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

Review: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-006. In Application 15A.8, why keep a continuous window crossing the period origin intact on an unfolded axis?

A. Every adjacent file is necessarily continuous

B. A modulo operation eliminates actual acquisition gaps

C. The overlap criterion can then ignore event duration

D. The coordinate origin must not destroy genuine sample continuity

Answer: D. Coordinate boundaries and physical gaps are different. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why the selected alternative fits: The coordinate origin must not destroy genuine sample continuity.

Distinguishing consideration: compare this with option A, “Every adjacent file is necessarily continuous”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

V011-C15-MCQ-007. What must supplement a preserved-file hash to support acquisition continuity?

A. The receiver model's advertised sample rate alone

B. A screenshot of the file's spectrum alone

C. A second copy of the same hash alone

D. Sample counters, sequences, validity flags and gap records

Answer: D. Hash agreement establishes byte consistency, not original sample completeness. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: Sample counters, sequences, validity flags and gap records.

Distinguishing consideration: compare this with option A, “The receiver model's advertised sample rate alone”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-008. Why use stored representation rather than ADC resolution in data-rate accounting?

A. Headers are already included in converter resolution

B. ADC resolution always equals file word width

C. Complex samples contain only one component

D. Container width, components and packing determine stored bytes

Answer: D. A 12-bit converter can be stored in a 16-bit container. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: Container width, components and packing determine stored bytes.

Distinguishing consideration: compare this with option A, “Headers are already included in converter resolution”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-MCQ-009. Why can a sensitive receiver miss an intermittent signal?

A. Its usable time, frequency or state coverage may not include the event

B. A missed event proves the source is absent

C. Adequate sensitivity guarantees every event is recorded

D. Sensitivity fixes the revisit phase automatically

Answer: A. Time and configuration coverage are independent requirements. Source: §15.1 Probability of Intercept and Observation Strategy (p. 8676)

Why the selected alternative fits: Its usable time, frequency or state coverage may not include the event.

Distinguishing consideration: compare this with option B, “A missed event proves the source is absent”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Probability of Intercept and Observation Strategy.

Review: Chapter 15 — Probability of Intercept and Observation Strategy.

V011-C15-MCQ-010. Which evidence requirement typically needs more than an identifiable fragment?

A. Computing the nominal schedule period

B. Establishing that some qualifying fragment occurred

C. Preserving complete startup and event boundaries

D. Recording one valid sample already inside a declared fragment

Answer: C. Different scientific questions require different contiguous durations and context. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: Preserving complete startup and event boundaries.

Distinguishing consideration: compare this with option A, “Computing the nominal schedule period”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-MCQ-011. Which interval should define usable dwell?

A. The interval from tuning command to next command regardless of response

B. The display's acquisition-indicator interval alone

C. The interval remaining after demonstrated settling, recovery and validity exclusions

D. The saved file's nominal timestamp span without continuity checks

Answer: C. Commands, indicators and valid samples can have different boundaries.

Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: The interval remaining after demonstrated settling, recovery and validity exclusions.

Distinguishing consideration: compare this with option A, “The interval from tuning command to next command regardless of response”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-MCQ-012. Does Model 15A establish a detector threshold or false-alarm rate?

A. No; therefore timing geometry is never useful

B. Yes; uniform event phase implies perfect detection

C. Yes; union length determines both

D. No; detector validity is a separate prerequisite

Answer: D. The model isolates conditional capture opportunity. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: No; detector validity is a separate prerequisite.

Distinguishing consideration: compare this with option A, “No; therefore timing geometry is never useful”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-MCQ-013. What assumption permits capture probability to equal eligible-start union length divided by period?

A. Uniform event start phase over that period

B. Ignorance of the actual phase alone

C. A periodic event sharing the receiver clock

D. Equal numbers of saved files per hour

Answer: A. Uniformity is a stated event-phase law, not a default consequence of missing knowledge. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: Uniform event start phase over that period.

Distinguishing consideration: compare this with option B, “Ignorance of the actual phase alone”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-MCQ-014. What changes for a known fixed event phase?

A. Multiply file count by dwell fraction

B. Assign probability one half regardless of geometry

C. Use the uniform length ratio as the actual deterministic outcome

D. Evaluate whether that phase belongs to the eligible set

Answer: D. A deterministic coverage statement replaces an unsupported uniform average. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: Evaluate whether that phase belongs to the eligible set.

Distinguishing consideration: compare this with option A, “Multiply file count by dwell fraction”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-MCQ-015. In Application 15A.4, when is the eligible-start set empty?

A. Whenever a window crosses the period origin

B. Whenever the event begins before the window

C. Whenever the phase distribution is uniform

D. When required overlap exceeds the event or usable-window duration

Answer: D. No interval intersection can exceed either interval's length. Source: §15.7 Application 15A.4: Reject an impossible overlap requirement (p. 8688)

Why the selected alternative fits: When required overlap exceeds the event or usable-window duration.

Distinguishing consideration: compare this with option A, “Whenever a window crosses the period origin”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.4: Reject an impossible overlap requirement.

V011-C15-MCQ-016. For one feasible window, what is the unfolded eligible-start length?

A. $D-b-2r$

B. $D+b-2r$

C. $D+b+r$

D. D alone in every case

Answer: B. Subtract the derived interval endpoints. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: $D+b-2r$.

Distinguishing consideration: compare this with option A, "$D-b-2r$"; that competing statement does not meet the question's stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-MCQ-017. Why is the single-window periodic result capped at one?

A. Every event becomes independent after one period

B. Modulo reduction cannot cover more than one full period of start phases

C. The detector always responds exactly once

D. The event amplitude is capped

Answer: B. Probability is union length divided by period. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: Modulo reduction cannot cover more than one full period of start phases.

Distinguishing consideration: compare this with option A, “Every event becomes independent after one period”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-MCQ-018. What is required before joining two adjacent recorded files as one continuous record?

A. Only matching center-frequency labels

B. Only adjacent displayed timestamps

C. Evidence that acquisition remained continuous across the boundary

D. Only equal file sizes

Answer: C. A file boundary need not be a gap, but continuity must be established.

Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Why the selected alternative fits: Evidence that acquisition remained continuous across the boundary.

Distinguishing consideration: compare this with option A, “Only matching center-frequency labels”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-MCQ-041. In Application 15A.7, a 5 ms event always starts at phase 50 ms and the usable window is [10,30] ms. How many of 100 identical repetitions qualify?

A. 0

B. 23

C. 100

D. 20

Answer: A. The fixed event remains outside the usable interval every time. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

Why the selected alternative fits: 0.

Distinguishing consideration: compare this with option B, “23”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

Review: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-042. In Application 15A.7, moving that usable window to [49,69] ms gives how many complete captures for the same 100 events?

A. 0

B. 100

C. 23

D. 20

Answer: B. Each fixed event [50,55] lies inside the new usable interval. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

Why the selected alternative fits: 100.

Distinguishing consideration: compare this with option A, “0”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

Review: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-043. In Application 15A.7, why is neither count a random estimate in the constructed fixed-phase example?

A. The event/schedule relationship is deterministic

B. The number 100 is too small for probability

C. All receiver experiments are deterministic

D. A fixed phase implies zero noise in every instrument

Answer: A. The stipulated timing specifies the outcome directly. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

Why the selected alternative fits: The event/schedule relationship is deterministic.

Distinguishing consideration: compare this with option B, “The number 100 is too small for probability”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

Review: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

V011-C15-MCQ-044. In Application 15A.8, for a continuous window [90,110] ms, b = 15 ms and r = 12 ms, what eligible starts occur before modulo reduction?

A. [90,95] ms

B. [87,98] ms

C. [78,113] ms

D. [0,10] ms

Answer: B. Keeping the 20 ms window intact gives 90+12−15 through 110−12.

Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why the selected alternative fits: [87,98] ms.

Distinguishing consideration: compare this with option A, “[90,95] ms”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-045. In Application 15A.8, what conditional probability follows in a 100 ms period?

A. 0.11

B. 0

C. 0.22

D. 0.20

Answer: A. The eligible interval is 11 ms long. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why the selected alternative fits: 0.11.

Distinguishing consideration: compare this with option B, “0”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-046. In Application 15A.8, an event starts at 95 ms and lasts 15 ms in that window. What overlap occurs?

A. 15 ms, so it qualifies

B. 12 ms exactly because r is 12

C. 10 ms, so it fails

D. 5 ms, so it fails

Answer: A. The event [95,110] lies wholly within [90,110]. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why the selected alternative fits: 15 ms, so it qualifies.

Distinguishing consideration: compare this with option B, “12 ms exactly because r is 12”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-047. In Application 15A.8, the same periodic schedule sees a 15 ms event starting at phase 0. What relevant overlap occurs?

A. 20 ms, so it qualifies

B. 10 ms, so it fails the 12 ms criterion

C. 0 ms because period zero is forbidden

D. 15 ms, so it qualifies

Answer: B. The event [0,15] overlaps the previous window [−10,10] for 10 ms.

Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why the selected alternative fits: 10 ms, so it fails the 12 ms criterion.

Distinguishing consideration: compare this with option A, “20 ms, so it qualifies”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

V011-C15-MCQ-048. In Application 15A.8, what error results from splitting the continuous [90,110] ms record at displayed zero?

A. The event duration doubles

B. A genuine rearm gap is preserved

C. Both apparent 10 ms pieces falsely seem too short for the 12 ms criterion

D. Capture probability becomes exactly correct by definition

Answer: C. The representational boundary is not a physical interruption. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why the selected alternative fits: Both apparent 10 ms pieces falsely seem too short for the 12 ms criterion.

Distinguishing consideration: compare this with option A, “The event duration doubles”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

V011-C15-MCQ-052. In Application 15A.10, for the same p and target 0.99, what minimum integer trial count is required?

A. 10

B. 19

C. 18

D. 17

Answer: C. The ceiling of the logarithmic ratio is 18; 17 falls below target. Source: §15.13 Application 15A.10: Solve for a conditional trial count and check the boundary (p. 8694)

Why the selected alternative fits: 18.

Distinguishing consideration: compare this with option A, “10”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.10: Solve for a conditional trial count and check the boundary.

Review: Chapter 15 — Application 15A.10: Solve for a conditional trial count and check the boundary.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-053. In Application 15A.10, why check the preceding integer when solving the trial-count formula?

A. To prove the phases are independent

B. To verify minimality and upward rounding at the boundary

C. To remove the need for the target probability

D. To estimate detector sensitivity from arithmetic alone

Answer: B. The model premises remain separate from the integer calculation.

Source: §15.13 Application 15A.10: Solve for a conditional trial count and check the boundary (p. 8694)

Why the selected alternative fits: To verify minimality and upward rounding at the boundary.

Distinguishing consideration: compare this with option A, “To prove the phases are independent”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Application 15A.10: Solve for a conditional trial count and check the boundary.

V011-C15-MCQ-060. What limits a trigger placed after narrow filtering?

A. It necessarily sees every full-rate sample feature

B. It cannot respond to precursors outside that trigger passband

C. It proves the complete event was retained

D. Its bandwidth equals the saved waveform's bandwidth in all designs

Answer: B. Trigger location determines what signal representation it observes.

Source: §15.14 Trigger Types and Pretrigger Context (p. 8695)

Why the selected alternative fits: It cannot respond to precursors outside that trigger passband.

Distinguishing consideration: compare this with option A, “It necessarily sees every full-rate sample feature”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Trigger Types and Pretrigger Context.

V011-C15-MCQ-075. Why test sustained writing for the planned duration?

A. Short bursts can be buffered despite inadequate long-run throughput

B. Storage capacity alone guarantees continuity

C. A file hash reveals all prior buffer overruns

D. Peak benchmark speed always equals sustained speed

Answer: A. The steady recording path and failure indicators must be exercised.

Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: Short bursts can be buffered despite inadequate long-run throughput.

Distinguishing consideration: compare this with option B, “Storage capacity alone guarantees continuity”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-MCQ-076. Which representation information is required to interpret native sample words?

A. Byte order, signedness, scale, packing and channel/component arrangement

B. Only center frequency

C. Only the total file size

D. Only converter nominal bit depth

Answer: A. The same bytes can represent different values under different conventions. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: Byte order, signedness, scale, packing and channel/component arrangement.

Distinguishing consideration: compare this with option B, “Only center frequency”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-MCQ-077. What does an explicit gap map preserve?

A. The waveform values that were never captured

B. A proof that every gap can be interpolated exactly

C. Missing intervals and the relation between sample index and elapsed time

D. A replacement for clock history

Answer: C. Analyses assuming uninterrupted uniform sampling should use valid segments. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: Missing intervals and the relation between sample index and elapsed time.

Distinguishing consideration: compare this with option A, “The waveform values that were never captured”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-MCQ-078. What should a derived spectrum identify beyond its picture?

A. Source, interval, channel, calibration, scale and processing parameters

B. Only the output image hash

C. Only its plotted peak frequency

D. Only the analyst's preferred window name

Answer: A. Reproduction requires the actual declared measurement chain. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: Source, interval, channel, calibration, scale and processing parameters.

Distinguishing consideration: compare this with option B, “Only the output image hash”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-MCQ-079. What is the purpose of a second analysis implementation?

A. Generate a visually similar plot regardless of scaling

B. Reproduce the declared quantity and expose convention or implementation differences

C. Replace the need for native samples

D. Guarantee both implementations are correct merely by agreement

Answer: B. Independent checks are stronger when inputs and conventions are explicit. Source: §15.18 Reproducible Analysis and Derived Products (p. 8706)

Why the selected alternative fits: Reproduce the declared quantity and expose convention or implementation differences.

Distinguishing consideration: compare this with option A, “Generate a visually similar plot regardless of scaling”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Reproducible Analysis and Derived Products.

Review: Chapter 15 — Reproducible Analysis and Derived Products.

V011-C15-MCQ-080. Why preserve manual exclusions and threshold decisions?

A. They affect the result and its reproducibility

B. Only automated processing can affect a result

C. Manual choices are always negligible

D. They can be reconstructed uniquely from the final image

Answer: A. The analysis chain includes human decisions. Source: §15.18 Reproducible Analysis and Derived Products (p. 8706)

Why the selected alternative fits: They affect the result and its reproducibility.

Distinguishing consideration: compare this with option B, “Only automated processing can affect a result”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Reproducible Analysis and Derived Products.

Review: Chapter 15 — Reproducible Analysis and Derived Products.

V011-C15-MCQ-082. What additional timing record is needed when correlating receiver data with another system's logs?

A. The receiver's carrier-frequency accuracy alone

B. A common time basis with known uncertainty and clock history

C. Matching timestamp text formats only

D. Equal file creation dates

Answer: B. Clock corrections, time zones and other timing conventions can affect alignment. Source: §15.17 Metadata, Time, and Site Context (p. 8705)

Why the selected alternative fits: A common time basis with known uncertainty and clock history.

Distinguishing consideration: compare this with option A, “The receiver's carrier-frequency accuracy alone”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Metadata, Time, and Site Context.

Review: Chapter 15 — Metadata, Time, and Site Context.

Copyright 2026, James M. Atkinson

V011-C15-MCQ-083. Why retain human-readable notes alongside automated logs?

A. They record reasons for changes and unexpected conditions not captured by settings alone

B. They replace rapid machine state logging

C. They prove every recorded setting was valid

D. They eliminate all operator-dependent uncertainty

Answer: A. The records provide complementary context. Source: §15.17 Metadata, Time, and Site Context (p. 8705)

Why the selected alternative fits: They record reasons for changes and unexpected conditions not captured by settings alone.

Distinguishing consideration: compare this with option B, “They replace rapid machine state logging”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Metadata, Time, and Site Context.

Review: Chapter 15 — Metadata, Time, and Site Context.

V011-C15-MCQ-084. Before a negative coverage claim, what four stages should be reconciled?

A. Raw, plotted, colored and printed traces

B. Purchase, delivery, installation and invoicing dates

C. Nominal, advertised, estimated and preferred bandwidth

D. Planned, commanded, valid and successfully preserved coverage

Answer: D. A plan or command does not establish the data actually retained. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: Planned, commanded, valid and successfully preserved coverage.

Distinguishing consideration: compare this with option A, “Raw, plotted, colored and printed traces”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-MCQ-085. Can a clean recording of one band establish absence outside its instantaneous passband?

A. Only if the file is large

B. Yes, after enough averaging

C. No

D. Yes, if its noise floor is low

Answer: C. The observation has a frequency-domain scope. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: No.

Distinguishing consideration: compare this with option A, “Only if the file is large”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-MCQ-086. Does high conditional capture probability for one burst model establish absence of all emissions?

A. No; other durations, schedules or detector failures remain outside the model

B. Yes; probabilities above 0.99 are universal

C. Yes; uniform phase covers every waveform class

D. No; probabilities can never support any bounded statement

Answer: A. The event class and prerequisites limit the conclusion. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: No; other durations, schedules or detector failures remain outside the model.

Distinguishing consideration: compare this with option B, “Yes; probabilities above 0.99 are universal”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-MCQ-090. For 40 MS/s,2 channels,2 components and 16 bits/component, what is uncompressed payload rate?

A. 160 MB/s

B. 640 MB/s

C. 320 MB/s

D. 80 MB/s

Answer: C. 40 million$\times 2 \times 2 \times \frac{16}{8}$=320 million bytes per second, using decimal units.

Source: §15.22 Hypothetical Applied Calculation: Triggering, Burst Capture, Recording, Metadata, and Reproducibility (p. 8712)

Why the selected alternative fits: 320 MB/s.

Distinguishing consideration: compare this with option A, “160 MB/s”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Hypothetical Applied Calculation: Triggering, Burst Capture, Recording, Metadata, and Reproducibility.

Review: Chapter 15 — Hypothetical Applied Calculation: Triggering, Burst Capture, Recording, Metadata, and Reproducibility.

V011-C15-MCQ-092. A 12-bit ADC's samples are stored in 16-bit containers. Which width enters byte-rate calculation?

A. 16 bits

B. 28 bits by adding both widths

C. 12 bits regardless of container

D. 4 bits because only overhead matters

Answer: A. The stored representation determines payload bytes. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why the selected alternative fits: 16 bits.

Distinguishing consideration: compare this with option B, “28 bits by adding both widths”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-FIB-052. In Application 15A.8, an event beginning 95 ms has _____ ms overlap with 90–110 ms.

Answer: 15. Its full interval is 95–110 ms. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why this term is required: “15” completes the stated technical proposition.

Question context: In Application 15A.8, an event beginning 95 ms has _____ ms overlap with 90–110 ms

Basis and qualification: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Copyright 2026, James M. Atkinson

V011-C15-FIB-053. In Application 15A.8, an event beginning at phase 0 has only _____ ms overlap with the relevant crossing record.

Answer: 10. It intersects −10–10 ms over 0–10 ms. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why this term is required: “10” completes the stated technical proposition.

Question context: In Application 15A.8, an event beginning at phase 0 has only _____ ms overlap with the relevant crossing record

Basis and qualification: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Copyright 2026, James M. Atkinson

V011-C15-FIB-054. In Application 15A.8, splitting the crossing record at zero falsely creates two _____ ms pieces.

Answer: 10. Neither apparent piece can meet 12 ms, despite actual continuity.

Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why this term is required: “10” completes the stated technical proposition.

Question context: In Application 15A.8, splitting the crossing record at zero falsely creates two _____ ms pieces

Basis and qualification: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Copyright 2026, James M. Atkinson

V011-C15-FIB-055. In Application 15A.8, a period origin is a coordinate boundary, not necessarily an acquisition _____.

Answer: gap. Metadata must distinguish representational and physical boundaries.

Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Why this term is required: “gap” completes the stated technical proposition.

Question context: In Application 15A.8, a period origin is a coordinate boundary, not necessarily an acquisition _____

Basis and qualification: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

V011-C15-FIB-097. A timestamp without clock _____ is not a complete timing measurement.

Answer: history. Corrections, reference state and conventions can change its meaning. Source: §15.17 Metadata, Time, and Site Context (p. 8705)

Why this term is required: “history” completes the stated technical proposition.

Question context: A timestamp without clock _____ is not a complete timing measurement

Basis and qualification: Chapter 15 — Metadata, Time, and Site Context.

Review: Chapter 15 — Metadata, Time, and Site Context.

V011-C15-FIB-098. Negative coverage claims reconcile planned, commanded, valid and successfully _____ intervals.

Answer: preserved. Only the actual retained observation supports the claim. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Why this term is required: “preserved” completes the stated technical proposition.

Question context: Negative coverage claims reconcile planned, commanded, valid and successfully _____ intervals

Basis and qualification: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-FIB-099. In the relay case, extra pretrigger data establish temporal order but not unique _____.

Answer: causation. A switch transient, newly admitted signal or shared control remain alternatives. Source: §15.23 Hypothetical Case Adjudication: Triggering, Burst Capture, Recording, Metadata, and Reproducibility (p. 8713)

Why this term is required: “causation” completes the stated technical proposition.

Question context: In the relay case, extra pretrigger data establish temporal order but not unique _____

Basis and qualification: Chapter 15 — Hypothetical Case Adjudication: Triggering, Burst Capture, Recording, Metadata, and Reproducibility.

Review: Chapter 15 — Hypothetical Case Adjudication: Triggering, Burst Capture, Recording, Metadata, and Reproducibility.

Essay Questions

[Essay instructions: Each essay must contain 3,500–5,000 words in total. Address the ten subject prompts below in the order presented, developing approximately 350–500 words for each prompt. Begin with an introduction establishing the question, scope and thesis. Conclude with a synthesis that draws together all ten prompts into one coherent closing argument. Count the introduction and conclusion within the overall word limit.]

V011-C15-ESSAY-001. Derive the single-window eligible-start interval from the positive contiguous-overlap criterion.

- Opening: Present a thesis that answers this precise question: Derive the single-window eligible-start interval from the positive contiguous-overlap criterion. Identify which evidence would falsify the proposed conclusion Source: §15.9 Application 15A.6: Take the union of overlapping capture-start sets (p. 8690)
- Core terminology and scope: Define single-window, eligible-start, interval in the question's particular technical setting; explain how positive, contiguous-overlap, criterion differ if that distinction would change the analysis of "Derive the single-window eligible-start interval from the positive contiguous-overlap criterion" Source: §15.9 Application 15A.6: Take the union of overlapping capture-start sets (p. 8690)
- Problem statement and purpose: Frame the actual measurement or decision in the question. Define a,D,b,r and the unfolded event interval Source: §15.9 Application 15A.6: Take the union of overlapping capture-start sets (p. 8690)
- Physical and computational context: Reconstruct the physical, mathematical or software mechanism connecting the single-window eligible-start interval from the positive contiguous-overlap criterion to the claimed result, following "Application 15A.4: Reject an impossible overlap requirement"; name the intermediate states and measurable outputs Source: §15.7 Application 15A.4: Reject an impossible overlap requirement (p. 8688)
- Assumptions, conditions and reference planes: State the testable assumptions, configuration states and reference planes for the

single-window eligible-start interval from the positive contiguous-overlap criterion. Derive both endpoint inequalities and feasibility then explain union reduction and the uniform-phase probability Source: §15.7 Application 15A.4: Reject an impossible overlap requirement (p. 8688)

- Analytical framework: Identify the equation, calibration or evidential decision test in “Application 15A.7: Keep a deterministic repeated miss deterministic” that resolves the question about the single-window eligible-start interval from the positive contiguous-overlap criterion; derive the relevant result with units and stated validity conditions Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)
- Evidence and method: Specify the native observations, control records and calculations that would resolve the single-window eligible-start interval from the positive contiguous-overlap criterion. Keep detector prerequisites separate Source: §15.9 Application 15A.6: Take the union of overlapping capture-start sets (p. 8690)
- Worked application or illustrative case: Build a worked example of “the single-window eligible-start interval from the positive contiguous-overlap criterion”, addressing this associated condition: Define a,D,b,r and the unfolded event interval. Define a,D,b,r and the unfolded event interval Source: §15.7 Application 15A.4: Reject an impossible overlap requirement (p. 8688)
- Alternative explanations and failure modes: Construct two plausible technical explanations for “the single-window eligible-start interval from the positive contiguous-overlap criterion”. Using “Application 15A.7: Keep a deterministic repeated miss deterministic”, specify a

discriminator and the result expected under each explanation Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

- Uncertainty and evidential limits: Quantify or bound the uncertainties that matter to the single-window eligible-start interval from the positive contiguous-overlap criterion, including the effect of missing measurements and inconsistent operating conditions Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)
- Scholarly synthesis and implications: Explain what the result about the single-window eligible-start interval from the positive contiguous-overlap criterion authorises the investigator or engineer to claim, and what stronger proposition remains unsupported Source: §15.9 Application 15A.6: Take the union of overlapping capture-start sets (p. 8690)
- Closing: Conclude by answering “Derive the single-window eligible-start interval from the positive contiguous-overlap criterion” using only the demonstrated evidence; state the remaining decisive verification step Source: §15.9 Application 15A.6: Take the union of overlapping capture-start sets (p. 8690)

V011-C15-ESSAY-002. Compare point, fragment and complete-event capture for the 10–30 ms window in a 100 ms schedule.

- Opening: Present a thesis that answers this precise question: Compare point, fragment and complete-event capture for the 10–30 ms window in a 100 ms schedule. Identify which evidence would falsify the proposed conclusion Source: §15.6 Application 15A.3: Require the whole burst (p. 8687)
- Core terminology and scope: Define point, fragment, complete-event in the question's particular technical setting; explain how capture, window, schedule differ if that distinction would change the analysis of "Compare point, fragment and complete-event capture for the 10–30 ms window in a 100 ms schedule" Source: §15.6 Application 15A.3: Require the whole burst (p. 8687)
- Problem statement and purpose: Frame the actual measurement or decision in the question. Calculate 0.20 for a point,0.199 for a complete 0.1 ms event,0.23 for b = 5/r = 1 and 0.15 for whole 5 ms Source: §15.6 Application 15A.3: Require the whole burst (p. 8687)
- Physical and computational context: Reconstruct the physical, mathematical or software mechanism connecting point, fragment and complete-event capture for the 10–30 ms window in a 100 ms schedule to the claimed result, following "Application 15A.1: Distinguish a point observation from full capture of a short event"; name the intermediate states and measurable outputs Source: §15.4 Application 15A.1: Distinguish a point observation from full capture of a short event (p. 8685)

Copyright 2026, James M. Atkinson

- Assumptions, conditions and reference planes: State the testable assumptions, configuration states and reference planes for point, fragment and complete-event capture for the 10–30 ms window in a 100 ms schedule. Explain the different questions and why recognizable fragments do not establish startup or full-frame preservation Source: §15.4 Application 15A.1: Distinguish a point observation from full capture of a short event (p. 8685)
- Analytical framework: Identify the equation, calibration or evidential decision test in “Application 15A.2: Capture a burst when only part of it is required” that resolves the question about point, fragment and complete-event capture for the 10–30 ms window in a 100 ms schedule; derive the relevant result with units and stated validity conditions Source: §15.5 Application 15A.2: Capture a burst when only part of it is required (p. 8686)
- Evidence and method: Specify the native observations, control records and calculations that would resolve point, fragment and complete-event capture for the 10–30 ms window in a 100 ms schedule. Explain the different questions and why recognizable fragments do not establish startup or full-frame preservation Source: §15.6 Application 15A.3: Require the whole burst (p. 8687)
- Worked application or illustrative case: Build a worked example of “point, fragment and complete-event capture for the 10–30 ms window in a 100 ms schedule”, addressing this associated condition: Calculate 0.20 for a point,0.199 for a complete 0.1 ms event,0.23 for b = 5/r = 1 and 0.15 for whole 5 ms. Calculate 0.20 for a point,0.199 for a complete 0.1 ms event,0.23 for b = 5/r = 1 and 0.15 for whole 5

Discussion Questions

[Discussion instructions: For each discussion question, prepare approximately 500 spoken words for delivery over 2.5–3 minutes (approximately 167–200 words per minute). Address the ten subject prompts below in their stated order. Use the opening to frame the issue and the closing to synthesise the principal findings, conclusions and unresolved questions.]

Copyright 2026, James M. Atkinson

V011-C15-DISCUSSION-001. A survey is sensitive enough in a bench test but misses a periodic burst. What should be checked?

- 01. Moderator, opening proposition: Introduce the exact dispute, “A survey is sensitive enough in a bench test but misses a periodic burst. What should be checked?” Put this particular dispute to the panel: A survey is sensitive enough in a bench test but misses a periodic burst. What should be checked. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

- 02. Student A, terminology and scope: Agree the operational meanings of sensitive, bench, misses and periodic, burst, checked in “A survey is sensitive enough in a bench test but misses a periodic burst. What should be checked”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of A survey is sensitive enough in a bench test but misses a periodic burst; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §15.8 Application 15A.5: Remove settling and closing guards from nominal dwell (p. 8689)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Application 15A.5: Remove settling and closing guards from nominal dwell”. Separate sensitivity from opportunity and change schedule when a fixed miss is plausible Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §15.8 Application 15A.5: Remove settling and closing guards from nominal dwell (p. 8689)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A survey is sensitive enough in a bench test but misses a periodic burst; explain what each record

Copyright 2026, James M. Atkinson

can establish State what the existing record establishes, what it does not establish, and which further measurement would change your opinion. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “Application 15A.5: Remove settling and closing guards from nominal dwell”. Separate sensitivity from opportunity and change schedule when a fixed miss is plausible Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §15.8 Application 15A.5: Remove settling and closing guards from nominal dwell (p. 8689)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. Compare event phase with usable dwell, settling and rearm intervals, and examine passband and trigger capability Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate between them without changing the measurand. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

Copyright 2026, James M. Atkinson

- 08. Student D, answer to Student E: Design a discriminating experiment involving A survey is sensitive enough in a bench test but misses a periodic burst: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A survey is sensitive enough in a bench test but misses a periodic burst; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving A survey is sensitive enough in a bench test but misses a periodic burst: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Present a repeatable, authorised test with the

receiver settings, controlled variable, expected responses and a rejection criterion. Ask Student H to identify an alternative that could survive the proposed test. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

- 11. Student H, adversarial challenge and confounding alternatives: For the precise observation involving A survey is sensitive enough in a bench test but misses a periodic burst, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Question Student G about a specific artifact or uncontrolled variable. Demand a control experiment that would expose a false positive or incorrect source attribution. Source: §15.8 Application 15A.5: Remove settling and closing guards from nominal dwell (p. 8689)

- 12. Student G, revised experimental answer: Address Student H's confounding mechanism by revising the controlled test described in the preceding prompt. Design a discriminating experiment involving A survey is sensitive enough in a bench test but misses a periodic burst: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Say precisely what observation would lead the panel to retain, qualify or reject the conclusion. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

Copyright 2026, James M. Atkinson

- 13. Student I, uncertainty and inferential limits: Assess uncertainty and evidential scope for A survey is sensitive enough in a bench test but misses a periodic burst. Separate sensitivity from opportunity and change schedule when a fixed miss is plausible Explain the relevant statistical or calibration uncertainty, the range of defensible claims, and why the question cannot be settled by visual appearance or a single unqualified reading. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

- 14. Student J, Socratic challenge to Student I: For the precise observation involving A survey is sensitive enough in a bench test but misses a periodic burst, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Ask Student I whether the proposed uncertainty statement accounts for the actual receiver state, sample coverage and possible instrumental artifacts. Request an explicit statement of what evidence would reverse the conclusion. Source: §15.8 Application 15A.5: Remove settling and closing guards from nominal dwell (p. 8689)

- 15. Student I, quantified and qualified reply: Assess uncertainty and evidential scope for A survey is sensitive enough in a bench test but misses a periodic burst. Separate sensitivity from opportunity and

Copyright 2026, James M. Atkinson

change schedule when a fixed miss is plausible Respond point by point to Student J. Distinguish a verified observation from a conditional inference and name the missing datum, sensitivity test or uncertainty term that limits confidence. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

- 16. Student K, authority and evidential discipline: Determine which authority, calibration and reporting safeguards apply to the particular claim about A survey is sensitive enough in a bench test but misses a periodic burst and What should be checked; exclude protections irrelevant to the scenario Question Student F about the custody and reproducibility of the proposed records and ask Student G whether the discriminatory test remains within authorised laboratory and field boundaries. Source: §15.15 Verify the trigger at its actual signal-path location (p. 8697)

- 17. Peer panel, negotiated consensus and residual dissent: Draft a narrow consensus about “A survey is sensitive enough in a bench test but misses a periodic burst”, addressing “What should be checked”; specify the exact measurement or evidential gap on which the speakers still differ Require Students A, B, D, G and I to respond to at least one objection raised by another speaker before voting. Record both the narrow agreement and the specific contested

Copyright 2026, James M. Atkinson

proposition that remains unresolved. Source: §15.10 Application 15A.7: Keep a deterministic repeated miss deterministic (p. 8691)

- 18. Moderator, reasoned disposition and follow-up: Record a final recommendation on “A survey is sensitive enough in a bench test but misses a periodic burst. What should be checked”, specifying the next test, responsible measurement record and limit of the conclusion Summarise the strongest evidence for and against the resolution of “A survey is sensitive enough in a bench test but misses a periodic burst. What should be checked”. Allocate the next measurement and documentary action to named student roles, and require each participant to distinguish accepted evidence from an unsupported assertion. V011-C15-DISCUSSION-007. Two files have adjacent timestamps around a period origin. May they be joined for a contiguous criterion?

- 01. Moderator, opening proposition: Introduce the exact dispute, “Two files have adjacent timestamps around a period origin. May they be joined for a contiguous criterion?” Put this particular dispute to the panel: Two files have adjacent timestamps around a period origin. May they be joined for a contiguous criterion. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

- 02. Student A, terminology and scope: Agree the operational meanings of adjacent, timestamps, period and origin, joined, contiguous in “Two files have adjacent timestamps around a period origin. May they be joined for a contiguous criterion”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of Two files have adjacent timestamps around a period origin; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §15.26 Additional study: sample continuity, acquisition clocks and the difference between stored bytes and observed RF time (p. 8721)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “15. Additional study: sample continuity, acquisition clocks and the difference between stored bytes and observed…”. Require sample-counter and clock evidence that acquisition continued without a gap, distinguish file and coordinate boundaries, and preserve any genuine rearm interruption Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §15.26 Additional study: sample continuity, acquisition clocks and the difference between stored bytes and observed RF time (p. 8721)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original

Copyright 2026, James M. Atkinson

trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of Two files have adjacent timestamps around a period origin; explain what each record can establish State what the existing record establishes, what it does not establish, and which further measurement would change your opinion. Source: §15.27 Evidence-grade metadata and reproducible processing (p. 8726)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “15. Additional study: sample continuity, acquisition clocks and the difference between stored bytes and observed…”. Require sample-counter and clock evidence that acquisition continued without a gap, distinguish file and coordinate boundaries, and preserve any genuine rearm interruption Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §15.26 Additional study: sample continuity, acquisition clocks and the difference between stored bytes and observed RF time (p. 8721)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. Require sample-counter and clock evidence that acquisition continued without a gap, distinguish file and coordinate boundaries, and preserve any

genuine rearm interruption Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate between them without changing the measurand. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

- 08. Student D, answer to Student E: Design a discriminating experiment involving Two files have adjacent timestamps around a period origin: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of Two files have adjacent timestamps around a period origin; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §15.27 Evidence-grade metadata and reproducible processing (p. 8726)

Copyright 2026, James M. Atkinson

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving Two files have adjacent timestamps around a period origin: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Present a repeatable, authorised test with the receiver settings, controlled variable, expected responses and a rejection criterion. Ask Student H to identify an alternative that could survive the proposed test. Source: §15.11 Application 15A.8: Preserve one contiguous window across the period origin (p. 8692)

- 11. Student H, adversarial challenge and confounding alternatives: For the precise observation involving Two files have adjacent timestamps around a period origin, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Question Student G about a specific artifact or uncontrolled variable. Demand a control experiment that would expose a false positive or incorrect source attribution. Source: §15.26 Additional study: sample continuity, acquisition clocks and the difference between stored bytes and observed RF time (p. 8721)

- 12. Student G, revised experimental answer: Address Student H’s confounding mechanism by revising the controlled test described in

V011-C15-DISCUSSION-014. A trigger time comes from a software packet. How can it support sample-level timing?

- 01. Moderator, opening proposition: Introduce the exact dispute, “A trigger time comes from a software packet. How can it support sample-level timing?” Put this particular dispute to the panel: A trigger time comes from a software packet. How can it support sample-level timing. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §15.14 Trigger Types and Pretrigger Context (p. 8695)

- 02. Student A, terminology and scope: Agree the operational meanings of trigger, comes, software and packet, support, timing in “A trigger time comes from a software packet. How can it support sample-level timing”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §15.14 Trigger Types and Pretrigger Context (p. 8695)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of A trigger time comes from a software packet; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §15.15 Verify the trigger at its actual signal-path location (p. 8697)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Verify the trigger at its actual signal-path location”. Measure the relation between software event, acquisition clock and stored sample apertures, retain latency and uncertainty, and avoid treating the packet timestamp as a direct sample time Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §15.15 Verify the trigger at its actual signal-path location (p. 8697)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A trigger time comes from a software packet; explain what each record can establish State what

the existing record establishes, what it does not establish, and which further measurement would change your opinion. Source: §15.29 Event-driven capture without treating quiet intervals as proof that no emission existed (p. 8733)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “Verify the trigger at its actual signal-path location”. Measure the relation between software event, acquisition clock and stored sample apertures, retain latency and uncertainty, and avoid treating the packet timestamp as a direct sample time Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §15.15 Verify the trigger at its actual signal-path location (p. 8697)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. Measure the relation between software event, acquisition clock and stored sample apertures, retain latency and uncertainty, and avoid treating the packet timestamp as a direct sample time Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate between them without changing the measurand. Source: §15.14 Trigger Types and Pretrigger Context (p. 8695)

Copyright 2026, James M. Atkinson

- 08. Student D, answer to Student E: Design a discriminating experiment involving A trigger time comes from a software packet: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §15.14 Trigger Types and Pretrigger Context (p. 8695)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A trigger time comes from a software packet; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §15.29 Event-driven capture without treating quiet intervals as proof that no emission existed (p. 8733)

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving A trigger time comes from a software packet: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion

V011-C15-DISCUSSION-018. A 12-bit converter is exported as 32-bit floating-point I/Q. Which representation governs storage planning?

- 01. Moderator, opening proposition: Introduce the exact dispute, “A 12-bit converter is exported as 32-bit floating-point I/Q. Which representation governs storage planning?” Put this particular dispute to the panel: A 12-bit converter is exported as 32-bit floating-point I/Q. Which representation governs storage planning. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

- 02. Student A, terminology and scope: Agree the operational meanings of converter, exported, representation and governs, storage, planning in “A 12-bit converter is exported as 32-bit floating-point I/Q. Which representation governs storage planning”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §15.19 Bind sample continuity, storage accounting and derived results (p. 8707)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of A 12-bit converter is exported as 32-bit floating-point I/Q; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §15.25 Continuity proofs for sampled RF records, missing-data masks and sustained throughput (p. 8718)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Continuity proofs for sampled RF records, missing-data masks and sustained throughput”. Distinguish acquisition resolution from container size and test the resulting sustained rate Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §15.25 Continuity proofs for sampled RF records, missing-data masks and sustained throughput (p. 8718)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A 12-bit converter is exported as 32-bit floating-point I/Q; explain what each record can establish

it does not establish, and which further measurement would change your opinion. Source: §15.14 Trigger Types and Pretrigger Context (p. 8695)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “Verify the trigger at its actual signal-path location”. Textual timestamp equality is insufficient Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §15.15 Verify the trigger at its actual signal-path location (p. 8697)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. Reconstruct clock histories, common time basis, trigger-to-sample relation and uncertainties before asserting temporal order Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate between them without changing the measurand. Source: §15.17 Metadata, Time, and Site Context (p. 8705)

- 08. Student D, answer to Student E: Design a discriminating experiment involving Two event logs appear simultaneous but use different clock corrections: specify the altered receiver state or

Copyright 2026, James M. Atkinson

source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §15.17 Metadata, Time, and Site Context (p. 8705)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of Two event logs appear simultaneous but use different clock corrections; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §15.14 Trigger Types and Pretrigger Context (p. 8695)

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving Two event logs appear simultaneous but use different clock corrections: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Present a repeatable, authorised test with the receiver settings, controlled variable, expected responses and a rejection criterion. Ask Student H to identify an alternative that could

Copyright 2026, James M. Atkinson

survive the proposed test. Source: §15.17 Metadata, Time, and Site Context (p. 8705)

- 11. Student H, adversarial challenge and confounding alternatives: For the precise observation involving Two event logs appear simultaneous but use different clock corrections, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Question Student G about a specific artifact or uncontrolled variable. Demand a control experiment that would expose a false positive or incorrect source attribution. Source: §15.15 Verify the trigger at its actual signal-path location (p. 8697)

- 12. Student G, revised experimental answer: Address Student H's confounding mechanism by revising the controlled test described in the preceding prompt. Design a discriminating experiment involving Two event logs appear simultaneous but use different clock corrections: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Say precisely what observation would lead the panel to retain, qualify or reject the conclusion. Source: §15.17 Metadata, Time, and Site Context (p. 8705)

Copyright 2026, James M. Atkinson

- 13. Student I, uncertainty and inferential limits: Assess uncertainty and evidential scope for Two event logs appear simultaneous but use different clock corrections. Textual timestamp equality is insufficient Explain the relevant statistical or calibration uncertainty, the range of defensible claims, and why the question cannot be settled by visual appearance or a single unqualified reading. Source: §15.14 Trigger Types and Pretrigger Context (p. 8695)

- 14. Student J, Socratic challenge to Student I: For the precise observation involving Two event logs appear simultaneous but use different clock corrections, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Ask Student I whether the proposed uncertainty statement accounts for the actual receiver state, sample coverage and possible instrumental artifacts. Request an explicit statement of what evidence would reverse the conclusion. Source: §15.15 Verify the trigger at its actual signal-path location (p. 8697)

- 15. Student I, quantified and qualified reply: Assess uncertainty and evidential scope for Two event logs appear simultaneous but use different clock corrections. Textual timestamp equality is insufficient Respond point by point to Student J. Distinguish a verified observation from a conditional inference and name the missing

- 14. Student J, Socratic challenge to Student I: For the precise observation involving A storage shortage prompts replacing native samples with screenshots, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Ask Student I whether the proposed uncertainty statement accounts for the actual receiver state, sample coverage and possible instrumental artifacts. Request an explicit statement of what evidence would reverse the conclusion. Source: §15.18 Reproducible Analysis and Derived Products (p. 8706)

- 15. Student I, quantified and qualified reply: Assess uncertainty and evidential scope for A storage shortage prompts replacing native samples with screenshots. Screenshots cannot restore discarded samples or processing context Respond point by point to Student J. Distinguish a verified observation from a conditional inference and name the missing datum, sensitivity test or uncertainty term that

Copyright 2026, James M. Atkinson

limits confidence. Source: §15.27 Evidence-grade metadata and reproducible processing (p. 8726)

- 16. Student K, authority and evidential discipline: Determine which authority, calibration and reporting safeguards apply to the particular claim about A storage shortage prompts replacing native samples with screenshots and What evidence decision is needed; exclude protections irrelevant to the scenario Question Student F about the custody and reproducibility of the proposed records and ask Student G whether the discriminatory test remains within authorised laboratory and field boundaries. Source: §15.16 Wideband Recording and Data Integrity (p. 8702)

- 17. Peer panel, negotiated consensus and residual dissent: Draft a narrow consensus about “A storage shortage prompts replacing native samples with screenshots”, addressing “What evidence decision is needed”; specify the exact measurement or evidential gap on which the speakers still differ Require Students A, B, D, G and I to respond to at least one objection raised by another speaker before voting. Record both the narrow agreement and the specific contested proposition that remains unresolved. Source: §15.20 Coverage Review and Storage Governance (p. 8709)

Copyright 2026, James M. Atkinson

- 18. Moderator, reasoned disposition and follow-up: Record a final recommendation on “A storage shortage prompts replacing native samples with screenshots. What evidence decision is needed”, specifying the next test, responsible measurement record and limit of the conclusion Summarise the strongest evidence for and against the resolution of “A storage shortage prompts replacing native samples with screenshots. What evidence decision is needed”. Allocate the next measurement and documentary action to named student roles, and require each participant to distinguish accepted evidence from an unsupported assertion. V011-C15-DISCUSSION-025. What would convince a reviewer that a capture claim is both technically valid and reproducible?

- 01. Moderator, opening proposition: Introduce the exact dispute, “What would convince a reviewer that a capture claim is both technically valid and reproducible?” Put this particular dispute to the panel: What would convince a reviewer that a capture claim is both technically valid and reproducible. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

- 02. Student A, terminology and scope: Agree the operational meanings of convince, reviewer, capture and claim, technically, reproducible in “What would convince a reviewer that a capture claim is both technically valid and reproducible”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of What would convince a reviewer that a capture claim is both technically valid and reproducible; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §15.4 Application 15A.1: Distinguish a point observation from full capture of a short event (p. 8685)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Application 15A.1: Distinguish a point observation from full capture of a short event”. Match the conclusion to that evidence rather than to display appearance Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §15.4 Application 15A.1: Distinguish a point observation from full capture of a short event (p. 8685)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of What would convince a

Copyright 2026, James M. Atkinson

reviewer that a capture claim is both technically valid and reproducible; explain what each record can establish State what the existing record establishes, what it does not establish, and which further measurement would change your opinion. Source: §15.27 Evidence-grade metadata and reproducible processing (p. 8726)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “Application 15A.1: Distinguish a point observation from full capture of a short event”. Match the conclusion to that evidence rather than to display appearance Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §15.4 Application 15A.1: Distinguish a point observation from full capture of a short event (p. 8685)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. A declared event criterion and detector prerequisites, usable schedule and phase law, verified continuous samples, bound metadata/calibration, exact processing and retained limitations Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate

Copyright 2026, James M. Atkinson

between them without changing the measurand. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

- 08. Student D, answer to Student E: Design a discriminating experiment involving What would convince a reviewer that a capture claim is both technically valid and reproducible: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of What would convince a reviewer that a capture claim is both technically valid and reproducible; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §15.27 Evidence-grade metadata and reproducible processing (p. 8726)

Copyright 2026, James M. Atkinson

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving What would convince a reviewer that a capture claim is both technically valid and reproducible: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Present a repeatable, authorised test with the receiver settings, controlled variable, expected responses and a rejection criterion. Ask Student H to identify an alternative that could survive the proposed test. Source: §15.2 Model 15A: calculate conditional event coverage from usable windows (p. 8677)

- 11. Student H, adversarial challenge and confounding alternatives: For the precise observation involving What would convince a reviewer that a capture claim is both technically valid and reproducible, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Question Student G about a specific artifact or uncontrolled variable. Demand a control experiment that would expose a false positive or incorrect source attribution. Source: §15.4 Application 15A.1: Distinguish a point observation from full capture of a short event (p. 8685)

- 12. Student G, revised experimental answer: Address Student H's confounding mechanism by revising the controlled test described in the preceding prompt. Design a discriminating experiment involving

Chapter 15 Answer Keys and Guidance

The essay and discussion guidance below identifies expected mechanisms, methods and evidence. A defensible alternative conclusion must state its assumptions, reasoning and limitations.

Copyright 2026, James M. Atkinson

Essay Guidance

V011-C15-ESSAY-001 — Define a,D,b,r and the unfolded event interval. Derive both endpoint inequalities and feasibility $r \leq min(b, D)$, then explain union reduction and the uniform-phase probability. Keep detector prerequisites separate.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-ESSAY-002 — Calculate 0.20 for a point,0.199 for a complete 0.1 ms event,0.23 for b = 5/r = 1 and 0.15 for whole 5 ms. Explain the different questions and why recognizable fragments do not establish startup or full-frame preservation.

Review: Chapter 15 — Application 15A.1: Distinguish a point observation from full capture of a short event.

V011-C15-ESSAY-003 — Account for settling, filter memory, AGC, rearming, transfer and validity flags. Reconstruct the guarded 4–27 ms example and 0.27 probability, explain transition-dependent guards, and distinguish commands from valid sample intervals.

Review: Chapter 15 — Application 15A.5: Remove settling and closing guards from nominal dwell.

V011-C15-ESSAY-004 — Use windows 10–25 and 28–43 ms with b = 20/r = 5, derive both intervals and 43 ms union. Explain the 7 ms double count and why union of qualifying starts does not add insufficient waveform fragments across the gap.

Review: Chapter 15 — Application 15A.6: Take the union of overlapping capture-start sets.

Copyright 2026, James M. Atkinson

V011-C15-ESSAY-005 — Use the phase 50 ms event and 10–30 ms window, then the 49–69 ms alternative. Distinguish a fixed outcome from a uniform-phase average, and specify evidence needed for randomized or independent repeated trials.

Review: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

V011-C15-ESSAY-006 — Use 90–110 ms,b = 15/r = 12 to derive 87–98 ms and 0.11. Evaluate starts 95 and 0, explain coordinate versus file versus physical boundaries, and identify metadata needed before joining files.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

V011-C15-ESSAY-007 — Use complement multiplication, derive the ceiling for interior p,q, and state p = 0,p = 1 and q 1 limits. Verify 18 versus 17 for p.23/q.99 and explain why the count is conditional, not universal.

Review: Chapter 15 — Application 15A.10: Solve for a conditional trial count and check the boundary.

V011-C15-ESSAY-008 — Use the product of independent miss probabilities, identify required phase assumptions, and explain why field timestamps or new labels do not establish independence. Preserve the actual adaptation rule and require a joint model or defensible bound for dependence.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

Copyright 2026, James M. Atkinson

V011-C15-ESSAY-009 — Identify full-rate, decimated, filtered or software statistics, test relevant edge/duration/level/modulation and prior quiet interval, compare saved sample time with trigger time, and use event pairs to measure holdoff and rearm.

Review: Chapter 15 — Verify the trigger at its actual signal-path location.

V011-C15-ESSAY-010 — Specify required leading and recovery context, ensure buffer samples are valid in the accepted state, retain transition flags and clock relationships, and distinguish whole-event evidence from a trigger-centered display.

Review: Chapter 15 — Trigger Types and Pretrigger Context.

V011-C15-ESSAY-011 — Compare bandwidth, sample rate, filtering, estimator latency and state control in the two paths. Give bounded examples of recorder passage without triggering and trigger response without sufficient valid waveform, then propose a reference test.

Review: Chapter 15 — Verify the trigger at its actual signal-path location.

V011-C15-ESSAY-012 — Calculate the 320 MB/s and 576 GB example, include container width, I/Q, channels, packing, overhead and reserve. Test sustained throughput for planned duration, monitor loss indicators and define controlled rollover/failure response.

Review: Chapter 15 — Hypothetical Applied Calculation: Triggering, Burst Capture, Recording, Metadata, and Reproducibility.

Copyright 2026, James M. Atkinson

V011-C15-ESSAY-013 — Explain what a closed-file hash binds and what it cannot establish. Use counters, sequence records, block lengths, flags and clock state to detect gaps or repeats; preserve a gap map and restrict estimators requiring uniform samples.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-ESSAY-014 — Track sample index against elapsed time and show how false transients or spectral behavior can arise. Require explicit gap/repeat events, continuity-aware segmentation and retained metadata rather than silently restoring expected file length.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-ESSAY-015 — Include representation, rate, center frequency, state, path, calibration, device/software, trigger, time reference and uncertainty, geometry and relevant conditions. Bind separate metadata to hashes and include human reasons for changes alongside automated logs.

Review: Chapter 15 — Metadata, Time, and Site Context.

V011-C15-ESSAY-016 — Retain native source and selected interval, scaling, calibration, receiver state, window/normalization, mixing/decimation and exclusions. Rerun with a second implementation where practical, use reference and noise-only controls, and report parameter sensitivity.

Review: Chapter 15 — Reproducible Analysis and Derived Products.

Copyright 2026, James M. Atkinson

V011-C15-ESSAY-017 — Describe selection by threshold and schedule, omitted quiet or precursor intervals, and the role of circular buffers. State what population the retained segments represent and what evidence would support a broader occupancy estimate.

Review: Chapter 15 — Wideband Recording and Data Integrity.

V011-C15-ESSAY-018 — Reconcile planned, commanded, valid and preserved intervals and passbands. Name event duration, overlap, phase law and detector prerequisites, retain excluded intervals and untested event classes, and avoid converting nonobservation into universal absence.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-ESSAY-019 — Explain temporal order and competing switch transient, newly admitted signal or shared-control hypotheses. Design a matched-reference static/bypass comparison with adequate sensitivity and preserve original and altered observations plus remaining attribution limits.

Review: Chapter 15 — Hypothetical Case Adjudication: Triggering, Burst Capture, Recording, Metadata, and Reproducibility.

V011-C15-ESSAY-020 — Define the intended cross-system comparison, clock source/history, time-zone and correction conventions, trigger-to-sample relation and uncertainty. Distinguish a timestamp string from a timing measurement and preserve state changes.

Review: Chapter 15 — Metadata, Time, and Site Context.

Copyright 2026, James M. Atkinson

V011-C15-ESSAY-021 — Identify needed native records, reserve and rollover, access controls, retention and disposition, incidental-content minimization and documented migration/deletion. Explain why derived products cannot silently replace the source needed for verification.

Review: Chapter 15 — Coverage Review and Storage Governance.

V011-C15-ESSAY-022 — Use a 2 ms event with 3 ms requirement to show empty eligibility regardless of dwell or repetition. Propose either a changed question or a justified multi-event estimator, explicitly stating new repeatability/coherence premises rather than claiming original success.

Review: Chapter 15 — Application 15A.4: Reject an impossible overlap requirement.

V011-C15-ESSAY-023 — Separate timing opportunity from threshold, SNR, false alarms, modulation recognition and minimum estimator duration. Describe controlled tests establishing prerequisites and show how failure of one changes the interpretation of a high geometric probability.

Review: Chapter 15 — Model 15A: calculate conditional event coverage from usable windows.

V011-C15-ESSAY-024 — Match instantaneous bandwidth, revisit, dwell, trigger and storage to each hypothesis; identify deterministic timing traps and needed state windows. Preserve the event-class-specific assumptions and avoid assigning one universal probability to the mixture without a model.

Review: Chapter 15 — Probability of Intercept and Observation Strategy.

Copyright 2026, James M. Atkinson

V011-C15-ESSAY-025 — Distinguish qualifying fragment, complete event, stated schedule coverage and reproducible result. For each specify continuity, event boundaries, usable intervals, phase assumptions, native data and processing evidence, with the corresponding limitation preserved.

Review: Chapter 15 — Verify the trigger at its actual signal-path location.

Copyright 2026, James M. Atkinson

Discussion Guidance

V011-C15-DISCUSSION-001 — Compare event phase with usable dwell, settling and rearm intervals, and examine passband and trigger capability. Separate sensitivity from opportunity and change schedule when a fixed miss is plausible.

Review: Chapter 15 — Probability of Intercept and Observation Strategy.

V011-C15-DISCUSSION-002 — Measure response validity after each relevant transition, identify settling/AGC/filter/rearm exclusions and compare commands to actual sample flags. Recompute coverage from demonstrated intervals.

Review: Chapter 15 — Application 15A.5: Remove settling and closing guards from nominal dwell.

V011-C15-DISCUSSION-003 — Require both boundaries and necessary context in one continuous record. Preserve the valid fragment observation while stating unknown leading/trailing portions and any missing startup information.

Review: Chapter 15 — Application 15A.3: Require the whole burst.

V011-C15-DISCUSSION-004 — Show that no timing schedule meets the stated one-event criterion, then reconsider the scientific question or define a new repeatable multi-event analysis. Do not improve the nominal probability by invalid arithmetic.

Review: Chapter 15 — Application 15A.4: Reject an impossible overlap requirement.

Copyright 2026, James M. Atkinson

V011-C15-DISCUSSION-005 — Derive each start set on the unfolded axis, reduce modulo period, merge overlaps and measure the union. Explain the difference between duplicate phases and physically combining fragmented data.

Review: Chapter 15 — Application 15A.6: Take the union of overlapping capture-start sets.

V011-C15-DISCUSSION-006 — No without a justified phase experiment; inspect fixed timing and change schedule or establish an appropriate joint model. More file count alone supplies no new phase opportunity.

Review: Chapter 15 — Application 15A.7: Keep a deterministic repeated miss deterministic.

V011-C15-DISCUSSION-007 — Require sample-counter and clock evidence that acquisition continued without a gap, distinguish file and coordinate boundaries, and preserve any genuine rearm interruption.

Review: Chapter 15 — Application 15A.8: Preserve one contiguous window across the period origin.

V011-C15-DISCUSSION-008 — No; examine periodic operation, shared clocks and trigger coupling or controlled randomization. State the actual phase model and do not infer independence from distinct timestamps.

Review: Chapter 15 — Application 15A.9: Calculate repeated capture only under independent start phases.

V011-C15-DISCUSSION-009 — Check event duration, usable window, required overlap, detector prerequisites and independent phase law. Recalculate for the actual conditions and retain boundary checks.

Review: Chapter 15 — Application 15A.10: Solve for a conditional trial count and check the boundary.

Copyright 2026, James M. Atkinson

V011-C15-DISCUSSION-010 — Preserve the adaptation rule and actual sequence, analyze the resulting conditional or joint experiment, and avoid assigning the old expression without matching assumptions.

Review: Chapter 15 — Application 15A.9: Calculate repeated capture only under independent start phases.

V011-C15-DISCUSSION-011 — Characterize trigger bandwidth and latency relative to saved data, choose a suitable trigger path or criterion, and retain the demonstrated distinction. Do not assume recorder presence guarantees trigger detection.

Review: Chapter 15 — Verify the trigger at its actual signal-path location.

V011-C15-DISCUSSION-012 — Holdoff, recovery or rearm behavior was not covered; vary controlled separation and inspect valid samples and trigger state. Bound the usable schedule accordingly.

Review: Chapter 15 — Verify the trigger at its actual signal-path location.

V011-C15-DISCUSSION-013 — No; inspect state timestamps and validity flags, characterize settling and retain only applicable context. Nominal depth does not prove continuous same-state evidence.

Review: Chapter 15 — Verify the trigger at its actual signal-path location.

V011-C15-DISCUSSION-014 — Measure the relation between software event, acquisition clock and stored sample apertures, retain latency and uncertainty, and avoid treating the packet timestamp as a direct sample time.

Review: Chapter 15 — Verify the trigger at its actual signal-path location.

Copyright 2026, James M. Atkinson

V011-C15-DISCUSSION-015 — Sustained writing in the planned configuration, buffer exhaustion, thermal and clock behavior, rollover and overrun indicators. Capacity and burst speed alone do not establish continuity.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-DISCUSSION-016 — Only unchanged preserved bytes relative to the hash, not original continuity. Use sequence counters and block records, preserve the repeat event and limit affected analyses.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-DISCUSSION-017 — The index-to-time relation and boundary waveform are changed, potentially creating false spectral features. Retain a gap map and use valid segments or a separately justified estimator.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-DISCUSSION-018 — The actual 32-bit two-component export, including channel count and overhead. Distinguish acquisition resolution from container size and test the resulting sustained rate.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

V011-C15-DISCUSSION-019 — The sample is selected by trigger and schedule and omits untriggered periods. Define the retained population and seek continuous or otherwise modeled exposure information for broader occupancy claims.

Review: Chapter 15 — Wideband Recording and Data Integrity.

Copyright 2026, James M. Atkinson

V011-C15-DISCUSSION-020 — Check selected interval/channel, scale, state, correction, window/normalization, decimation, exclusions and software version. Compare a second implementation of the same declared quantity and preserve manual choices.

Review: Chapter 15 — Reproducible Analysis and Derived Products.

V011-C15-DISCUSSION-021 — Reconstruct clock histories, common time basis, trigger-to-sample relation and uncertainties before asserting temporal order. Textual timestamp equality is insufficient.

Review: Chapter 15 — Metadata, Time, and Site Context.

V011-C15-DISCUSSION-022 — Restrict it to actually preserved passband and usable intervals with the tested event class and detector capability. Identify outside-band and excluded intervals explicitly.

Review: Chapter 15 — Bind sample continuity, storage accounting and derived results.

Cross-volume technical interface. S001-V020(Field Operations Evidence Handling Chain of Custody and Litigation Support) governs the broader transfer, sealing and custody record;S001-V021(Case Studies Deployment Lessons and Institutional Practice) provides comparative field practice; andS001-V025(Cross Volume Analytical Index Subject Taxonomy and Reference Apparatus) provides the topical retrieval route. A receiver artifact must still be distinguished here from an external emission by controlled changes in gain, reference input, antenna, localisation, time base and independent instrumentation, with alternative hypotheses, negative controls and uncertainty preserved in the finding.

Copyright 2026, James M. Atkinson

V011-C15-DISCUSSION-023 — Compare static or bypassed switch operation with a matched desired reference and adequate detection capability. Retain alternatives of generated transient, newly admitted signal or common control until discriminated.

Review: Chapter 15 — Hypothetical Case Adjudication: Triggering, Burst Capture, Recording, Metadata, and Reproducibility.

V011-C15-DISCUSSION-024 — Identify native records required for the authorized purpose and later verification, preserve them with access controls, and document any disposition. Screenshots cannot restore discarded samples or processing context.

Review: Chapter 15 — Coverage Review and Storage Governance.

V011-C15-DISCUSSION-025 — A declared event criterion and detector prerequisites, usable schedule and phase law, verified continuous samples, bound metadata/calibration, exact processing and retained limitations. Match the conclusion to that evidence rather than to display appearance.

Review: Chapter 15 — Verify the trigger at its actual signal-path location.

Copyright 2026, James M. Atkinson

Chapter Glossary

CAPTURE FEASIBILITY: The existence of an event start that can satisfy the declared capture criterion under the model's domain. For one contiguous window, the positive required overlap cannot exceed the event or window duration. An impossible criterion produces zero probability before any averaging over start phases is considered.

CIRCULAR BUFFER: A recording arrangement that continually retains a rolling interval, replacing older data until selected content is preserved. Triggered extraction can provide pre-event context while controlling retained storage. That context remains usable only if its samples are valid and belong to the accepted configuration and continuous timing record.

CLOSING GUARD: An excluded interval at the end of a nominal acquisition during which the retained data no longer satisfy the declared validity conditions. It reduces the usable window independently of an initial settling guard. Coverage calculations must use the remaining contiguous interval and state the reasons for the exclusion.

CONDITIONAL CAPTURE PROBABILITY: The probability of meeting a defined acquisition geometry under a stated event-phase distribution and separately established signal and detector conditions.

CONTIGUOUS-OVERLAP CRITERION: A capture requirement met by one uninterrupted event-window intersection of at least a specified positive duration.

DEAD TIME: Interval during which an acquisition system cannot accept or record another event.

Copyright 2026, James M. Atkinson

DECIMATED TRIGGER: A trigger operating on a rate-reduced representation of the signal. The preceding filter and sample-rate change can alter the event information and timing available to it. Its behavior must be checked against the saved waveform and intended event criterion rather than assumed equivalent to a full-rate trigger.

DERIVED-PRODUCT LINEAGE: The documented relationship connecting a spectrum, decode, image, table or other processed result to its source record, selected interval, channel, calibration and exact processing decisions. It enables reproduction of the declared quantity. Visual similarity to a screenshot is insufficient when the underlying scaling, normalization or sample selection differs.

ELIGIBLE-START UNION: The union, over usable windows and schedule periods, of event start times that satisfy the declared capture criterion.

EVENT DURATION: The elapsed length assigned to an event in the stated capture model. It is distinct from the duration of signal that the intended measurement requires. Detecting a fragment, measuring a steady portion and preserving startup or the whole event can impose different criteria on the same event duration.

EVENT START PHASE: The event's start-time position relative to a repeating observation schedule, considered modulo the schedule period. A particular event can have a fixed phase, while a probabilistic model assigns a distribution to possible phases. These are different statements, and ignorance of the encountered phase does not itself justify uniformity.

Copyright 2026, James M. Atkinson

FILE ROLLOVER: The controlled transition from one recording file to the next during a longer acquisition. It keeps files manageable while requiring preserved chronology and explicit continuity evidence across the boundary. Successful closure and hashing of individual files do not by themselves show that no samples were lost or repeated between them.

FULL-RATE TRIGGER: A trigger operating on the undecreased sample stream at its stated processing location. Its relation to saved samples still depends on filtering, comparator behavior and latency. The contrast with a decimated trigger identifies a path distinction; it does not establish universal timing or sensitivity performance.

GAP MAP: An explicit record of missing or otherwise unusable sample intervals and their positions in the acquisition chronology. It prevents simple concatenation from erasing the true elapsed interval or creating a false signal discontinuity. Analyses requiring uninterrupted uniform sampling must respect the mapped boundaries.

INDEPENDENT CAPTURE TRIALS: Trials whose relevant event phases and capture outcomes satisfy the independence needed by the stated probability model. Counting separate files or repeated commands does not establish this property. Under the additional common-probability premise, the complement of all misses gives the probability of at least one capture.

MINIMUM TRIAL COUNT: The smallest positive integer number of qualifying trials that meets a specified conditional capture target under the stated probability assumptions. Model 15A rounds the interior logarithmic result upward and checks the preceding integer. Zero-probability, certain-capture and exactly-one target cases require their separate endpoint rules.

Copyright 2026, James M. Atkinson

PAYLOAD BYTE RATE: The byte rate occupied by the declared uncompressed sample components before additional headers, padding, timing records or file-system effects. It depends on actual stored component width, channel count and sample rate. Sustained recording capability must include the extra traffic and cannot be inferred solely from this ideal payload calculation.

PERIODIC REDUCTION: Representation of times by their positions within one declared schedule period. Model 15A first derives eligible event starts on an unfolded axis and then reduces their union modulo the period. This order preserves a genuinely contiguous window crossing the chosen origin and avoids mistaking the displayed split for an acquisition gap.

POINT-OBSERVATION LIMIT: The separate idealization in which an instantaneous event must lie inside a usable observation window. It is not obtained by treating zero overlap as a successful empty intersection. Model 15A relates it to the limit of fully capturing a shrinking event while preserving the intended detection criterion.

PRETRIGGER: Recorded interval preceding the condition that initiated an acquisition.

PROBABILITY OF INTERCEPT: Probability that an observation strategy overlaps and detects an event meeting the stated criterion.

REARM INTERVAL: The period required for the acquisition or trigger system to become ready for another qualifying event. A real rearm gap remains an exclusion in the usable-window model. Adjacent-looking timestamps or saved files do not establish continuous availability across that interval.

Copyright 2026, James M. Atkinson

RECORD CONTINUITY: Verified absence or documented location of gaps, repeats, lost packets, or clock discontinuities in sampled data.

REPEATED SAMPLE BLOCK: A portion of acquisition data preserved more than once where the intended sample sequence should advance. It can corrupt timing and spectral interpretation even if the final file is internally readable and unchanged. Sequence and sample-domain records are needed to distinguish it from a legitimately repeating waveform.

REPRODUCIBILITY: Ability to obtain a consistent result from preserved data and a documented method.

REQUIRED OVERLAP: The positive contiguous duration that an event and one usable acquisition window must share to meet the declared capture criterion. It must not exceed either duration for capture to be feasible. Combining disconnected fragments does not satisfy this one-window criterion unless the measurement question is explicitly changed.

REVISIT PERIOD: The elapsed period after which the declared observation schedule repeats. Model 15A places usable windows and event-start phases relative to that period. A nominal revisit specification must retain settling, rearm and transfer gaps; repeated schedules can continue to miss an event whose phase is locked to them.

SAMPLE COUNTER: A recorded index or count associated with the acquisition sequence. When its semantics, rollover and reset behavior are known, it helps test whether intended samples were retained in order. A plausible file duration or a stable byte hash does not replace this sample-domain continuity evidence.

Copyright 2026, James M. Atkinson

SCHEDULE PHASE LOCKING: A persistent relationship between event timing and the repeating observation schedule. It can place each event in the same usable interval or the same blind interval. Repeating the schedule then does not create independent opportunities, and a formula based on independent trial phases cannot be applied without changing or justifying the experiment.

SEGMENTED ACQUISITION: Recording selected intervals, often in response to triggers, instead of preserving every intervening sample. It can reduce storage but omit context and bias occupancy estimates. Each segment and the gaps between segments must retain their timing and validity information before an analysis assumes continuous observation.

SEQUENCE-NUMBER CHECK: A comparison of declared block or packet sequence identifiers to detect missing, repeated or reordered portions of a record. Its interpretation depends on the acquisition protocol and reset behavior. It supports continuity assessment alongside sample counters, block lengths, overrun flags and clock status.

SETTLING GUARD: An initial interval excluded from a nominal dwell because tuning, filtering, gain control or another state transition has not yet produced usable data. It reduces the window available to meet the event criterion. Its duration must follow the applicable observed or justified response rather than the mere completion of a control command.

Copyright 2026, James M. Atkinson

STORED SAMPLE REPRESENTATION: The actual encoding of recorded sample components, including real or complex form, container width, signedness, byte order, packing, interleaving and scaling. It determines payload accounting and interpretation. Converter resolution alone does not specify that representation, and an exported format can use a different byte rate for the same sample sequence.

TRIGGER HOLDOFF: A declared interval or condition during which further trigger acceptance is inhibited after a trigger event. It affects the ability to record a second closely spaced event. Characterization with controlled event pairs is therefore needed in addition to a successful isolated-event test.

TRIGGER HYSTERESIS: A dependence of trigger-state transitions on distinct entry and release conditions, used in the declared trigger logic. It affects whether and when nearby signal excursions generate new events. Its settings and behavior belong to the capture configuration rather than being inferred from the displayed trigger threshold alone.

TRIGGER LATENCY: The delay between the relevant event at a specified trigger-path boundary and the trigger indication or action. Its value and variability depend on the trigger location and processing. A known-stimulus test must relate it to the stored sample times; a trigger label alone does not identify that relationship.

TRIGGER PATH: The part of the receiver processing chain observed by the trigger decision. It may use full-rate samples, a decimated channel, filtering or a software statistic, giving it a different bandwidth or delay from the saved waveform. The event can therefore be present in one path without satisfying the other’s condition.

Copyright 2026, James M. Atkinson

UNEQUAL-TRIAL PROBABILITIES: Different declared single-trial capture probabilities used when the experiment varies across trials. Their miss probabilities can be multiplied only when the relevant independence assumptions remain justified. Assigning different numbers to correlated trials does not remove the need for a joint model or a defensible bound.

UNIFORM PHASE ASSUMPTION: The assumption that event starts are equally distributed over a schedule period. Under it, Model 15A converts the merged eligible-start duration into a conditional capture probability. A synchronized or concentrated event process requires its own distribution or a deterministic coverage statement rather than this convenient average.

USABLE ACQUISITION WINDOW: One contiguous interval in which the retained samples meet the stated configuration, settling, continuity and detector prerequisites.

Chapter 16. Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance

Copyright 2026, James M. Atkinson

16.1 Artifact Taxonomy and Competing Explanations

Receiver artifacts include residual responses, local-oscillator leakage, images, aliases, ADC clipping, quantization products, intermodulation, reciprocal mixing, filter ringing, detector transients, AGC effects, software false locks, dropped-sample splatter, clock spurs, power-converter noise, cable common mode, and enclosure leakage. Environmental alternatives include legitimate transmitters, reradiation, passive intermodulation, conducted coupling, reflections, and state-dependent emissions. The initial observation is classified as unexplained until these mechanisms are challenged.[1]

Artifact analysis starts with architecture. The practitioner asks where in the chain the component could have been created and which control lies before or after that location. Input attenuation tests products created after the attenuator differently from external signals. Preselection challenges out-of-band parents. Sample-rate and LO changes challenge aliases and spurs. Antenna termination, receiver substitution, clock substitution, channel swap, and physical relocation alter other mechanisms.

16.2 Challenge-Test Design

A challenge test changes one causal factor while preserving enough of the measurement to compare results. Useful challenges include attenuation, preamplifier bypass, filter insertion, alternate antenna, polarization, location, power source, reference clock, sample rate, tuning plan, detector, bandwidth, and controlled operation of a suspected device. The predicted outcomes for at least two competing explanations are written before the test.

Tests should not be selected only after seeing a favorable result. Sequence, blinding, held-out captures, and negative controls reduce confirmation bias. A test that risks loss of evidence, interference with service, or unauthorized collection requires approval. The record includes unsuccessful challenges and instances where the system state could not be reproduced.

16.3 Localize an artifact by changing the stage that could create it

Begin with an architecture map that places each plausible mechanism before or after accessible controls. A component generated in a broadband preamplifier should respond differently to bypassing that amplifier than one already present at the antenna connector. A sampled alias should move according to the actual sample-rate and frequency mapping. A conversion image should follow the signed translation and preselection described in Model 4A. A control transient should depend on the preceding state and timing. Write those predictions before changing the setup so the test has a discriminating purpose.

A useful challenge changes the error structure while preserving the desired comparison. Substituting a second receiver can be informative, but shared antennas, splitters, clocks, power supplies, software, or calibration files can preserve the original cause. Conversely, a substitution can change sensitivity enough to hide a real signal. Carry a known reference through both configurations so absence on the second path can be interpreted against its demonstrated capability. Agreement and disagreement both require this context.

Use the new model families as a connected diagnostic vocabulary. Model 4A predicts conversion sign and candidate spur movement, while Chapter 10 follows mixing and sampling in the digital path. Model 5A explains an identified control trajectory within its tested range. Models 6A and 6B separate amplitude, phase, and frequency behavior. Model 7A shows which alignment or normalization can conceal a demodulation defect. Models 12A

Copyright 2026, James M. Atkinson

and 12B distinguish deterministic timing errors from covariance-dependent phase effects. Model 15A separates a missed observation from a demonstrated absence.

A single successful challenge rarely establishes attribution. An unexplained line that scales like an external signal may still be an instrument emission coupled through the antenna path. A line that disappears with a terminated input may have depended on a mismatched termination or a removed external nonlinear element. A plausible decoded identifier may be repeated, stale, or generated by a false lock. Preserve the narrow consequence of each test and combine only those consequences whose assumptions are supported.

Copyright 2026, James M. Atkinson

16.4 Receiver challenges with interacting controls

A comparison made by changing one control is conditional on the settings that remain fixed. A result obtained with a particular clock, input route, and gain state therefore answers a narrower question than whether the changed component can ever create the observed response. Interaction matters when changing one factor has a different consequence at another setting of a second factor. The NIST experimental-design treatment explains why isolated one-factor searches can miss that dependence. In receiver work, the practical remedy is to examine the relevant combinations of states and retain their individual results. This does not require assigning statistical odds to a suspected artifact. It requires specifying what is changed, what is observed, and which alternative explanations each comparison can distinguish.[2]

Define factors by physical changes rather than by convenient front-panel labels. Selecting an external reference can alter frequency calibration, common-mode coupling, phase continuity, and cable connections. Bypassing an antenna switch can alter insertion loss, impedance, the signal route, and control transients. A nominal clock factor and a nominal switch factor are consequently bundles of physical consequences until those consequences are characterized. Record the actual reference source, connections, termination, switch route, control state, and acquisition

configuration for each combination. The existing conversion, timing, overload, and uncertainty models supply the interpretation of these changes. The experiment tests their applicability in the installed chain; a menu selection by itself does not isolate a mechanism.

Copyright 2026, James M. Atkinson

16.4.1 Arrange the comparisons before examining their outcomes

For two controls with two declared settings each, observe all four combinations when they are physically meaningful: original reference with the switch in circuit, original reference with the switch bypassed, alternate reference with the switch in circuit, and alternate reference with the switch bypassed. Compare the switch states within each reference state, then compare the reference states within each switch state. This arrangement exposes whether the apparent effect depends on the companion setting. It is the experimental-design principle of crossing the factor levels, applied here as a diagnostic record. If a combination is unavailable or changes the measurement beyond a defensible comparison, record that missing condition explicitly. The remaining observations cannot silently supply the absent comparison.[3]

Before acquisition, define the response at a physical reference plane. It might be corrected power within a declared frequency interval, a phase relation under the established timing convention, or the occurrence of a waveform meeting a prespecified criterion. Retain the underlying records as well as the summary. A binary label such as "visible" can conceal an ordinary sensitivity change: the same component may fall below a display threshold after additional loss, even though its physical source persists. Compare the

Kuyatt, Guidelines for Evaluating and Expressing the Uncertainty of NIST Measurement Results, NIST Technical Note 1297, 1994 edition (September 1994), Appendix A, A.1–A.5, https://www.nist.gov/pml/nist-technical-note-1297/nist-tn-1297-appendix-law-propagation-uncertainty. The functional and covariance framework is used within its stated scope; the synthetic ranges, examples and recoverability conclusions are original.

Copyright 2026, James M. Atkinson

relevant continuous observations and the demonstrated observation limits before interpreting a conditional disappearance. Differences expressed as linear power, logarithmic level, and threshold crossings answer different questions. The response definition must remain fixed across the comparisons.

An interaction in the recorded response narrows the explanatory problem but does not locate the responsible circuit. A clock cable and a switch enclosure might jointly complete a coupling path. They might instead change receiver sensitivity in a way that becomes consequential only with a particular blocker. A third, uncontrolled condition could also track the selected combinations. Use the architecture map to propose discriminating follow-up observations, such as an independently observed reference-path emission or a calibrated desired signal in the presence of the admitted blocker. The combination record supports these next tests. It does not convert a dependence between settings into proof that either named component is defective.

Copyright 2026, James M. Atkinson

16.4.2 Preserve comparable observation capability

Carry an appropriate known reference through every configuration whose nondetection will support the conclusion. The reference should exercise the function being compared: a narrow continuous tone tests a different capability from a short burst, a wideband modulated waveform, or a weak signal beside a strong blocker. A check at one comfortable level does not establish performance near the observation limit. The NIST check-standard method emphasizes a representative, repeatable characteristic and an accumulated record of its behavior. Applied to this receiver comparison, the reference record should show the relevant frequency mapping, signal transfer, and acquisition capability in each state, with the accepted limits and their basis preserved.[4]

Keep the reference plane and the scope of each correction explicit. In the published vector-receiver calibration examined in Chapter 14, Kast and colleagues require the same reference plane, or correction for added paths, and bind calibration validity to the hardware and software configuration. The same discipline prevents a diagnostic comparison from treating a bypass cable, changed preselector, or new digital correction as transparent. Use the corrections already supported for each state and propagate their relevant shared uncertainties under Model 14B. If a state lacks the

Randa, Uncertainties in NIST Noise-Temperature Measurements, NIST Technical Note 1502 (March 1998), §§3.9–3.10, 16–17, https://nvlpubs.nist.gov/nistpubs/Legacy/TN/nbstechnicalnote1502.pdf. These sources distinguish receiver noise from source and path contributions; the scalar assumptions and synthetic cases are stated in Model 2B.

Copyright 2026, James M. Atkinson

necessary characterization, its record can still reveal an observation, but it cannot support the same quantitative comparison as a characterized state.[5]

Separate the settled state from the transition used to reach it. Changing a reference can require relocking; switching a route can create an impulse; returning to a gain setting can preserve a recovery history. Model 5A supplies the conditions under which its retained recovery law applies, while Chapters 12 and 15 define timing and usable acquisition intervals. Mark transition records and settled records separately. If the phenomenon occurs only during switching, that transient becomes the object of a dedicated comparison. Removing it from a settled-state analysis must not erase it from the evidence record or turn it into an unexplained exclusion.

5 H. T. Friis, “Noise Figures of Radio Receivers,” Proceedings of the IRE 32, no. 7 (July 1944): 419–22, https://doi.org/10.1109/JRPROC.1944.232049. The publisher’s abstract was read for the historical network, component, mismatch, and measurement framing. The full paper was not accessed; Model 2B supplies its own stated derivation and working conventions.

Copyright 2026, James M. Atkinson

16.4.3 Interpret hypothetical receiver records

Hypothetical clock-and-switch comparison. The unexplained component is reproducibly observed with the original reference and the switch in circuit. It is absent under the declared criterion in the other three combinations, while a suitable known reference remains observable in each configuration. This pattern makes the joint configuration a useful suspect and motivates a test of the connecting reference and return paths. It does not show that both components independently generate the line. Nor does it prove that the line is absent below the demonstrated observation limits in the other states. Preserve the actual level records, the interval over which the component could have been observed, and whether each return to the original combination reproduced the response.

Hypothetical preselection-and-gain comparison. A spur appears at high gain with broadband admission but not with a selective input filter. At lower gain it is absent in both input states. The pattern is compatible with an overload mechanism requiring both strong admitted parents and sufficient downstream gain. Its interpretation still depends on measured parent levels, desired-reference transfer, and source or combiner purity under Model 11A. The filter may also change mismatch or the gain-control trajectory. Test those alternatives before assigning the product to a particular stage. A four-state pattern provides more informative evidence than a single successful filter insertion, while retaining the physical qualifications already developed in Chapters 3 and 11.

Hypothetical detector-and-record comparison. A decoder reports valid-looking identifiers only when a permissive synchronization rule is applied to

Copyright 2026, James M. Atkinson

one recording. A stricter rule removes them, while known valid reference records survive both rules. Reprocess an independently obtained noise-only record under both rules and preserve its outputs. This crossed comparison can expose dependence on both the processing rule and the input record. It cannot retrospectively establish the origin of every event in the field recording. Training the stricter rule on those same events also changes the claim: an independently retained validation record is needed to assess performance beyond the examples used to choose the rule. Model 7A supplies the existing distinction between fitted and held-out data.

Copyright 2026, James M. Atkinson

16.4.4 Record repetition and the limits of the design

Revisit each configuration through fresh acquisitions. Replotting one capture, changing its display scale, or dividing it into overlapping windows does not repeat the intervention. The NIST factorial-design example uses replication to examine variability and randomizes run order to reduce systematic association with extraneous changes. A receiver sequence should likewise avoid assigning every occurrence of one setting to a different operating period from its comparison setting. Where relocking, access, or a stable source interval restricts the order, document the restriction and the corresponding limit. The temporal-control analysis belongs beside this design; it is not replaced by the four configuration labels.[6]

Blocking groups observations under a declared nuisance condition, such as the same source operating interval or the same installed fixture. It does not make that condition disappear. Keep the relevant comparisons within each group where practicable and preserve group membership in the analysis. If all original-reference observations come from one session and all alternate-reference observations from another, reference state and session are inseparable in those data. Repetition within either session cannot repair the missing cross-session comparison. Report the ambiguity and obtain the

Copyright 2026, James M. Atkinson

missing combinations when the source and installation permit a meaningful repeat.[7]

Release the diagnostic record with the planned combinations, actual run order, physical states, source conditions, control-reference results, accepted records, excluded intervals, and unresolved alternatives. State whether the evidence shows a response associated with one setting, a response conditional on another setting, or insufficient comparability. Use the existing correction and uncertainty treatments for numerical differences and the existing capture model for observation opportunity. This procedural design introduces no numerical likelihood assignment or new universal receiver law. Its contribution is a more discriminating experiment: a later examiner can see precisely which combinations were observed and which causal distinctions the available records still cannot settle.

A. Instrument challenge table

Challenge	Possible external response	Possible artefact response
Attenuation	Approx. 1:1	Nonlinear slope
Preselector	Path-loss change	Product may vanish
LO retune	Stable RF location	Spur can move
Second receiver	May corroborate	Often differs
Dummy load	RF input removed	Spur may remain

B. Evidentiary decision flow

These are indicative challenge outcomes, not universal signatures. Report confounders and retained raw records.

Figure 86. Receiver artefact challenge matrix.

Table 16A. Select challenges that distinguish competing mechanisms

Copyright 2026, James M. Atkinson

Observation and proposed mechanism	Discriminating change	Confounder to control
An apparent signal may be a conversion image	Change the conversion plan or image-selective preselection and use Model 4A	Desired transfer and receiver state may also change
A discrete product may originate in a nonlinear stage	Change a parent or attenuation before the proposed stage and use Model 11A	Sources and combiners may generate the same product
An elevated floor may be reciprocal mixing	Vary admitted blocker power and retain fixed weighted output calibration under Model 11B	AGC, direct blocker leakage and baseline drift can mimic the change
A missing burst may reflect schedule coverage	Change usable windows and compare against Model 15A	The detector and event population must remain applicable
A phase discrepancy may be timing or common-reference behavior	Compare calibrated channels, reset histories and reference paths under Models 12A and 12B	Shared error and wrapped-phase ambiguity can conceal the cause

Copyright 2026, James M. Atkinson

16.5 Integration with Direction, Wireline, Optical, and Physical Evidence

Receiver evidence becomes stronger when it converges with independent domains. Direction finding or spatial gradients can localize a source, but indoor multipath and antenna phase centers must be considered. Wireline current, network logs, optical activity, acoustic state, power demand, thermal change, or physical inspection can establish a mechanism or authorization status. The time bases and configuration states of those observations must be reconciled.

Cross-domain agreement is not automatic independence. Sensors can share power, clocks, cables, software, or environmental causes. A receiver and current probe may both respond to the same instrument clock. Multiple software tools may use the same underlying decoder. The report identifies common dependencies and gives greater weight to evidence that changes the error structure.

Copyright 2026, James M. Atkinson

16.6 Findings, Reports, and Decision Ladders

A receiver report distinguishes normal occupancy, authorized device emissions, measurement artifact, installation defect, unexplained signal, unauthorized transmitter, and confirmed technical-surveillance function. A confirmed function requires more than frequency and modulation. It requires physical or operational linkage, information path, authorization status, reproducible behavior, and evidence continuity. Intermediate categories are useful because they support proportionate action without overstating certainty.

Reports include purpose, authority, equipment and configuration, coverage, baselines, calibration, uncertainty, significant observations, challenge tests, competing explanations, derived content handling, limitations, and recommendations. Figures and traces are linked to native data. Unresolved signals are described with enough detail for follow-up, including time, location, bandwidth, detector, antenna, state, and why the available evidence did not support attribution.

Copyright 2026, James M. Atkinson

16.7 Reconcile evidence without assigning unsupported probabilities

Equation 31 compares corrected levels at the same reference plane. Its value is meaningful only after gain, loss, bandwidth, detector, and relevant state changes have been reconciled. Chapter 14 supplies the correction and covariance-aware uncertainty framework. If the corrected difference lies within the justified uncertainty, the observations are compatible at that resolution. Compatibility does not prove one mechanism, and a difference beyond the interval identifies a discrepancy to investigate rather than naming its cause automatically.

Equation 32 states what a likelihood comparison would require: defined hypotheses and defensible probability models for the actual data and selection procedure. It is not used here to assign numerical odds to artifact or attribution categories. A visually persuasive coincidence, a count of favorable tests, or an expert confidence label does not supply those likelihoods. If calibrated statistical models are unavailable, report the observed discriminating consequences and remaining alternatives directly instead of manufacturing a numerical ratio.

Avoid multiplying evidence contributions as if each were independent merely because they have different labels. Two receivers may share a clock; a spectral plot and an EVM report may derive from the same samples; a trigger record and a software log may share one timestamp source. Their agreement can be technically useful while providing less independent confirmation than their count suggests. Document the common

Copyright 2026, James M. Atkinson

dependencies and seek an observation that changes the relevant coupling, timing, or processing path.

A negative control should test a specific alternative. A terminated input examines residual responses in that configuration. A known reference tests sensitivity and scale at its chosen frequency and level. A noise-only record tests a detector under that noise condition. None covers every field state. Use controls that bracket the actual observation, and retain failures as well as passes. If a closing check fails, identify which earlier conclusions depend on the affected function and narrow or repeat them accordingly.

Copyright 2026, James M. Atkinson

16.8 Write findings that preserve the strength and limit of each test

Organize a technical finding around the question, the accepted data, the calculation or comparison, the challenge results, and the resulting inference. State whether the data establish detection, waveform classification, temporal correlation, localization, device linkage, or a more limited observation. Link each figure or table to the native record and configuration. Keep derived quantities beside their units, bandwidths, normalization, reference planes, and uncertainty so they remain interpretable outside the original instrument session.

For an unresolved component, describe the work that would most effectively discriminate the remaining explanations. A repeat at the same settings may improve repeatability without testing a different cause. A changed clock, alternate conversion plan, controlled source state, independent timing observation, or physical path substitution may provide more decisive information. Prioritize the change according to the current evidence and operational authority. Record why a proposed test was not performed if that omission limits the conclusion.

When a receiver artifact is established, preserve enough detail to make the correction reusable. Identify the configurations that exhibit it, the known stimulus or state transition, the predicted and observed response, the successful challenge, and the accepted mitigation. Avoid converting a narrow incident into a universal rule about all instruments or environments. A controlled artifact record should help another examiner reproduce the

Copyright 2026, James M. Atkinson

effect and determine whether the same explanation applies to a later observation.

Copyright 2026, James M. Atkinson

16.9 Acceptance, Maintenance, and Lifecycle Control

Receiver systems used for defensive work require acceptance tests after purchase, repair, firmware change, calibration, accessory change, or major software update. Acceptance covers sensitivity, amplitude and frequency accuracy, dynamic range, preselection, images, spurs, phase noise, sample continuity, trigger behavior, metadata, and the complete field path. A simple self-test or calibrated center-frequency tone is insufficient.

Maintenance records include calibration, repairs, battery and power-supply condition, connector and switch wear, fan and thermal state, clock performance, software dependencies, correction files, and known limitations. Regression captures with stable references reveal drift. Retired data formats and software are preserved or migrated with checks. Lessons from field artifacts are added to controlled challenge procedures without turning one incident into a universal rule.

Copyright 2026, James M. Atkinson

16.10 Program Governance and Peer Review

Receiver findings with significant operational, legal, or reputational consequence receive independent technical review. The reviewer receives native data, configurations, calculations, calibration records, challenge results, and competing explanations rather than only the final narrative. Disagreements are resolved through additional tests or disclosed limitations, not suppressed through editorial consensus.

Program governance maintains approved receiver configurations, competency records, proficiency tests, field check standards, data-retention rules, known artifact libraries, and correction histories. New methods are validated before routine use. The organization records errors and reversals so that its procedures improve without converting a single case into unsupported doctrine.

Copyright 2026, James M. Atkinson

16.11 Quantitative Model for Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance

Equation 1. Normalized attenuation response error

$$e_A = P_{2,\mathrm{corr}} - P_{1,\mathrm{corr}}$$

After correcting two traces for the applied attenuation or gain change, normalized response error e_A is their level difference at the same reference plane. A value outside combined uncertainty suggests compression, a product generated after the changed element, or another state change.

Equation 2. Likelihood ratio for competing hypotheses

$$\Lambda = \frac{p(D \mid H_1)}{p(D \mid H_0)}$$

A likelihood ratio compares how probable data D are under competing hypotheses H_1 and H_0 when valid models exist. It is not a substitute for defining the hypotheses, accounting for selection effects, or establishing legal standards of proof.

Equation 31 reuses the signed calibration and uncertainty treatment of Chapter 14. Equation 32 is a definition for already specified probability or density models, with a positive denominator for a finite ratio. This chapter does not assign those models or numerical odds. Its challenge tests remain mechanism comparisons with disclosed dependencies and unresolved alternatives.

Copyright 2026, James M. Atkinson

Table 1. Chapter 16 receiver controls and interpretation limits

Control or quantity	Measurement or record	Interpretation value	Failure or limitation
Artifact challenge	Predicted mechanism, changed element, preserved controls, outcome, and uncertainty	Discriminates receiver-created and environmental components	Post hoc tests without predictions are vulnerable to bias
Cross-domain correlation	Time, location, state, calibration, shared dependencies, and independent controls	Can establish mechanism and attribution	Several sensors may share the same artifact source
Finding category	Normal, authorized, artifact, defect, unexplained, unauthorized, or confirmed function	Supports proportionate decisions	Frequency or decoding alone is not functional attribution
Lifecycle control	Acceptance, regression, calibration, repairs, software, corrections, and known limits	Maintains confidence across deployments	Self-test and a single reference tone do not test the full chain

16.12 Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance

A component reads -83.0 dBm with zero input attenuation and -93.2 dBm after 10.0 dB attenuation. Correcting the second trace gives -83.2 dBm, a 0.2 dB difference within the 0.7 dB combined uncertainty. This scaling is consistent with an external signal but does not by itself establish its source or authorization.

Copyright 2026, James M. Atkinson

16.13 Hypothetical Case Adjudication: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance

A weak burst correlates with keyboard activity and appears on two receiver channels. Investigation shows both channels share an external clock and antenna switch. An optical sensor independently records LED activity, but no field component remains when the receiver is powered from an isolated reference and the switch is bypassed. This joint intervention implicates the shared measurement path but changes two conditions at once. The report retains an instrumentation-artifact hypothesis pending separate reference and switch challenges, reversal checks, and verification that the modified chain still detects a suitable known reference. The optical observation remains evidence of LED activity and does not independently establish an RF source.

Copyright 2026, James M. Atkinson

16.14 Challenge-Test and Evidence Release Gate

Before a receiver observation becomes a reportable finding, the chain should be challenged through attenuation, preselection, antenna substitution, terminated-input tests, known-source injection, frequency-reference comparison, changed span and bandwidth, alternate receiver, time-domain correlation, and spatial movement. The test sequence must preserve the native data and the failed as well as successful hypotheses. A result that disappears under one challenge is not necessarily false, but the mechanism must be resolved before attribution.

Copyright 2026, James M. Atkinson

16.15 Close the receiver method through configuration-specific regression

A software, firmware, accessory, or repair change can alter several parts of the measurement chain at once. Select regression checks from the functions the deployed method actually uses: amplitude and noise calibration, frequency conversion, sample scaling, control recovery, modulation alignment, phase continuity, trigger geometry, and record integrity. Reuse the known references and accepted ranges that established those functions. A passing startup self-test is useful evidence about its covered functions, but it does not replace that configuration-specific comparison.

Preserve the prior accepted configuration and the changed configuration as distinct states until the relevant comparisons are complete. If a new correction or processing method changes reported results, rerun representative retained records and explain the difference. Keep both the original and revised derived products with their processing identities. This allows a later reviewer to distinguish a corrected interpretation from a change to the underlying observation.

The final release of a receiver finding should be bounded by the completed technical work. Unresolved calibration, discontinuous samples, unverified automatic state, or insufficient event coverage should remain visible in the conclusion. A method can still be useful within a narrower accepted domain. The purpose of lifecycle control is to preserve that known domain as equipment and software change, so future observations inherit tested capabilities and explicit limits rather than an undocumented history of apparently successful use.

16.16 Falsification-led survey closure and the evidential status of negative observations

A receiver survey should end with a structured confrontation of alternative explanations rather than with the assertion that no suspicious transmitter was found. The relevant proposition is bounded by a named event class, frequency-time opportunity, instrument validity, declared threshold and the controls actually applied. A negative result can be very useful when it narrows a practical decision under demonstrated coverage. It does not prove the universal absence of every possible intermittent, shielded, frequency-agile or otherwise unobserved source. The investigator should identify the strongest plausible mechanism that could defeat the test, then determine whether the existing observations discriminate it. Where the mechanism remains untested, the final report should preserve that limitation without collapsing into an uninformative declaration that anything is possible.

Construct an explicit falsification register with one row per claim. For a narrowband candidate, list instrument-generated spur, external emission, environmental intermodulation, unstable reference, configuration-transition product and incidental source-generated artefact as competing explanations where applicable. For each row record a predicted response to an intervention, the original and comparator measurement capabilities, what was observed, and the residual uncertainty. Alternate attenuation may test downstream product location; alternate antenna geometry may test spatial coupling; reference-source substitution may test clock-related products; a controlled shielded-source challenge may test the detector's

Copyright 2026, James M. Atkinson

susceptibility and observation window. None of these controls is infallible, but a coherent pattern of observations can progressively eliminate explanations without creating a false sense of certainty from any single screenshot.

A quantitative illustration clarifies the limits of a negative survey. Suppose an idealised event model assigns each of ten independent, valid observation opportunities a probability $p = 0.25$ of detecting an event, conditional on the source being active and the model being appropriate. The probability of zero detections under that model is $(1 - p)^{10} = 0.75^{10}$, approximately 0.0563. This is not a posterior probability that the source was absent, nor is it valid when the ten dwells share blind intervals or detection probabilities. If the opportunities are strongly dependent, the simple multiplication is wrong. The result can assist experimental design only with a defensible event model, validated receiver sensitivity and actual coverage records, including unsuccessful acquisition intervals.

A closure record should include the original technical question, authority and minimisation controls; the installed receiving path; the current calibration and checks; retained native data or stated lawful substitutes; configuration and clock histories; detected events and rejected hypotheses; negative tests and failed captures; and the final bounded conclusion. Separate what was directly measured from what was inferred using propagation, waveform classification or statistical assumptions. Note any shared error mechanisms among apparent corroborating instruments, and mark periods when the receiver could not have detected the stipulated event. The final review should be repeatable by someone who did not attend the engagement, and strong claims about an individual source should never

Copyright 2026, James M. Atkinson

rest solely on an instrument's internal classification label. The formality of this procedure is valuable because it turns an otherwise fleeting RF observation into a transparent piece of engineering evidence.

Copyright 2026, James M. Atkinson

16.17 An evidence-closure matrix that links physical tests to permissible forensic propositions

A survey report should distinguish an observation at an instrument output, a waveform classification, an inferred external source and a conclusion of legally relevant activity. Each step requires additional evidence. A narrow peak acquired with a declared detector and bandwidth can establish a bounded observation without establishing the identity or intent of an emitter. A modulation-family classification may be informative but still be confused by a receiver-generated product. A physical attribution may depend on geometry, coherent timing, antenna orientation, controlled equipment-state changes and exclusion of common error mechanisms. Legal characterisation adds further facts and jurisdiction-specific authority that cannot be supplied by RF measurements alone. A report that collapses these propositions is at risk even when its raw samples are technically excellent.

A structured alternative-hypothesis matrix gives every meaningful explanation a falsifiable prediction. For a component observed near one expected channel, list external emitter, local-oscillator leak, mixer product, ADC alias, unrecorded laboratory reference, cable common-mode current and algorithmic display artefact where physically plausible. For each hypothesis specify what should change under an independently authorised intervention: preselector state, input termination, antenna orientation, LO offset, sample rate, reference-clock substitution or controlled source power. Record the comparison's sensitivity, valid observation window and expected sign of the effect. A failed test does not automatically prove the favoured

Copyright 2026, James M. Atkinson

alternative; its power to discriminate depends on whether the purported mechanism would actually have been observed under the comparator conditions.

The meaning of independent corroboration deserves separate treatment. Two receiver enclosures connected through one splitter share the antenna path, external gain stage and potentially the same nonlinearity. Two analysis methods operating on the same clipped samples share the missing information. Two sensors with different antennas but one common noisy clock can show matching periodic features that originate in their reference distribution. The appropriate question is which error mechanisms differ, not how many displays agree. A direct source-on/source-off challenge can be powerful when authorised and controlled, but it may change the electromagnetic environment in several ways at once. A causal interpretation must account for that change and retain unsuccessful trials rather than treating agreement as a vote.

A reporting example shows the value of a bounded statement. Assume an independently calibrated receiver observed no events above threshold during 90 per cent of a stipulated 10-minute interval, while the remaining minute lacked valid capture because of an AGC state transition and subsequent buffer loss. The strongest direct negative conclusion is limited to the nine valid minutes, the tested band and defined event class. It does not establish absence during the other minute. If an event model assigns independent opportunities for detection, a probability-based inference may be possible, but that model and its independence assumption must be separately validated. A statement that the site was completely free of

Copyright 2026, James M. Atkinson

surveillance emissions is not supported by a record that did not observe the entire stipulated opportunity.

The closure matrix should contain the original task and lawful collection authority, configured receiving path, antenna and clock states, applicable calibration, source and combiner controls, sample validity, software processing lineage, uncertainty analysis, candidate observations, competing hypotheses, outcomes of challenges and final qualified statements. Required outputs should include native data where lawfully retainable, metadata and integrity digests, rejected tests, location and timing records and explicit scope exclusions. The final reviewer should be able to reconstruct not only the preferred interpretation but also why alternatives were weakened or retained. If source-to-claim verification is unfinished, mark it as a publication dependency rather than disguising it behind technical-sounding prose. Scientific authority arises from reproducible tests and bounded inference, not from the sheer length of a discussion.

Copyright 2026, James M. Atkinson

A release decision must specify evidence, limitations and unresolved hypotheses.

TECHNICAL INTERPRETATION

A defensible conclusion requires corroboration, traceable records and uncertainty accounting. Missing controls require an explicit qualification.

Figure 87. Evidence closure and qualified forensic findings.

16.18 Advanced technical expansion. Hypothesis-led artifact adjudication and bounded assurance

The final receiver investigation is not a contest to produce the most visually striking spectrum. It is an exercise in discriminating alternative physical explanations while preserving the limits of each test. A detected feature can arise from an external emitter, passive intermodulation in an installed junction, nonlinear amplification, oscillator or clock leakage, sample-rate aliasing, digital processing, conducted coupling or an interaction of several mechanisms. A defensible report should begin with a hypothesis register that specifies what each mechanism predicts and which controlled change would be informative. A list of hypothetical causes without predicted observable differences is not yet an experimental plan. It may encourage arbitrary equipment adjustment until one favourite explanation appears to fit.

Consider an illustrative component observed at 437.5 MHz. Under an external-emitter hypothesis, moving the antenna can change amplitude and phase according to propagation and polarisation, though a disappearance is not conclusive without comparable sensitivity. Under a mixer-product hypothesis, changing the local oscillator by a known amount may move the IF or calculated spur according to a signed mixing relation. Under a clock-leakage hypothesis, substituting a reference can change the feature or its spectral shape. Under a software-generated hypothesis, the component may appear only after a particular processing step and not in an independently retained raw record. Each intervention requires an explicit counterfactual prediction. Two features can coexist; finding an internal

Copyright 2026, James M. Atkinson

product does not exclude a genuine external signal at the same apparent frequency.

The strength of evidence depends on error independence. A second receiver that shares the same antenna, cable, power source, frequency reference and analysis application may reproduce the first instrument's fault. Conversely, an independently configured receiver may fail to reproduce a genuine brief event because its dwell timing or sensitivity differs. The comparison should map shared and separate signal paths, clocks, firmware, processing and environmental exposures. A useful corroboration experiment changes suspected common error mechanisms while preserving the capability to observe the claimed emission. If the comparison cannot meet that condition, its negative result is qualified rather than treated as exclusion. Independence is an engineering relationship among causal mechanisms, not simply a count of boxes present in the room.

An evidential matrix should distinguish direct observations from model-based inferences. The observation column identifies raw data, time range, frequency, state and measurement uncertainties. The prediction column states what each candidate explanation would imply under a specified intervention. The result column records which predictions were confirmed, contradicted or left untested. The inference column then uses precise verbs: detected, consistent with, classified, localised under stated assumptions, attributed with corroboration or unresolved. A measured reduction in a spectral peak after introducing input attenuation can support an overload-related interpretation, but the strength of that inference depends on whether the desired reference remained observable and whether gain

Copyright 2026, James M. Atkinson

compensation changed automatically. The matrix should record such confounding variables instead of suppressing them in the narrative.

Negative findings need an equally disciplined formulation. Suppose an engagement includes 24 hours of clock time, of which four hours are demonstrably invalid because of instrument reconfiguration, eight hours observe only a subset of the required bands, and twelve hours have validated coverage for a specific event class. The report cannot claim 24 hours of complete negative monitoring. It may state that no events meeting a defined criterion were detected during the twelve hours of relevant validated coverage, with the other intervals classified accurately. The 12/24 = 0.5 fraction is a duration-based coverage statistic, not a universal capture probability. Converting that fraction into a confidence bound requires a model of source activity, event timing, threshold performance and missed detections. The model itself should be disclosed and challengeable.

Forensic reproducibility also depends on maintaining a distinction between authentic historical record and later analytical product. An instrument trace, original I/Q recording, time-and-state log, calibrated transfer measurement, model fit and expert narrative have different epistemic statuses. A source-to-claim concordance should identify which specific record supports each consequential assertion and where professional judgement enters. The report must also preserve the limits of collection authority, the handling of incidental information, relevant access restrictions and the process by which exhibits were selected. Credibility is strengthened when unsuccessful tests and contradictory observations remain available to independent reviewers rather than being hidden behind the final hypothesis.

Copyright 2026, James M. Atkinson

The chapter should close with an operational lifecycle model. Instruments enter service through documented acceptance, remain in controlled use through configuration and calibration checks, and are suspended or qualified after consequential overload, firmware change, damaged accessory or unexplained deviation. A return-to-service record demonstrates only the functions and conditions exercised during its tests; it does not retroactively repair historical invalid acquisitions. Periodic regression tests using known references can reveal drift, but must be interpreted together with environmental controls and statistical repeatability. A final conclusion is thus a bounded statement about a particular measurement system, at particular times and under particular states, not a permanent declaration that the entire installation or institution is free of all conceivable emitters.

Copyright 2026, James M. Atkinson

16.19 From a spectral observation to an experimentally identifiable cause

The central problem of receiver-artifact examination is one of identifiability, not merely one of recognizing familiar spur patterns. An observed complex sample stream can arise from an external electric field, intermodulation within an amplifier, local-oscillator leakage, a clock-derived spur, an image response, conducted ingress, or a composite of these causes. Distinct causes can yield numerically similar carrier frequencies, powers and apparent modulation; even a repeated observation does not make the mapping from output to physical source unique. The appropriate inverse problem begins by specifying a candidate causal mechanism and predicting how it must respond to an intervention. If two mechanisms predict the same behaviour for all interventions undertaken, the experiment has not discriminated between them. It is not legitimate to resolve that ambiguity by selecting the more dramatic narrative. State the surviving equivalence class of explanations and the next measurement that would distinguish its members.

A useful model represents the retained record as $r(t)=F[x(t),q(t),e(t)]+a(t)$, where $x(t)$ is the external electromagnetic input at a named plane, $q(t)$ is the instrument's time-varying hardware and firmware state, $e(t)$ comprises the environmental and coupling conditions, F is the configured transformation, and $a(t)$ represents contributions not included in that declared transformation. This is a structural description rather than a claim that disturbances simply add independently. Overload may alter F itself, and feedback may make $q(t)$ depend on $x(t)$. A challenge must consequently

Copyright 2026, James M. Atkinson

identify which variables it holds constant, which it deliberately changes, and which it merely observes. A subsequent amplitude correction cannot repair the information lost when the mapping was nonlinear or when a critical state was not recorded. The examiner should capture native data before, during and after the intervention, along with reference-source state and instrument control transitions.

The most informative interventions are designed to generate incompatible predictions. A component that originates upstream of a switched attenuator should, within a validated linear state, change by the applied attenuation in the raw receiver indication. A component generated downstream need not do so. Yet a gain-control loop can conceal the predicted change, and a nonlinear product arising upstream may fall much faster than the applied attenuation. Therefore the question is not whether a peak moved by precisely the same number of decibels shown in a menu, but whether the observed response lies within a predeclared uncertainty enclosure for each candidate mechanism. The attenuation element itself must be measured, and its placement relative to the suspected generation stage must be established. Repeating the test at a different blocker level helps distinguish a linear path from a cubic product or a limiting response.

Copyright 2026, James M. Atkinson

16.20 An intervention matrix that separates mechanism, state and common error

Before acquisition, construct a matrix whose rows are competing explanations and whose columns are interventions: input termination, preselector substitution, antenna relocation, attenuation change, independent clock, independent receiver, separate power source, controlled source injection, and repeated acquisition after thermal settling. For each cell enter an expected direction and range of change, and a list of ways the intervention could fail to isolate the intended cause. This avoids the retrospective practice of declaring whichever manipulation happened to remove a peak to be definitive. A preselector can remove a genuine external signal that lies outside its passband, while a terminated input can change oscillator loading or internal cable coupling. The exercise is strongest when these side effects are quantified before interpreting the result.

Factorial testing is preferable to uncontrolled serial experimentation when two receiver settings interact. Suppose factors A and B represent an input attenuator and an optional preamplifier, each at two settled states. Write the four response values y00, y10, y01 and y11 at the same reference plane and under equivalent source conditions. The interaction contrast I=y11-y10-y01+y00 measures whether the combined effect departs from the sum of the individual changes in the chosen response scale. Decibel responses may be suitable for level comparisons under specified conditions, but a logarithmic contrast is not automatically an additive physical-power interaction. For a power balance, first transform to compatible linear watts and formulate the corresponding hypothesis. A significant I may be

Copyright 2026, James M. Atkinson

produced by gain control, compression or changed filter loading rather than by the emission being sought; test the mechanism with further targeted controls.

Randomise the order of repeatable laboratory challenges when drift or warm-up could otherwise masquerade as a response. An AABB sequence may confound the intervention with time; an ABBA or randomised blocked sequence can expose temporal trend if settling is measured and source conditions remain comparable. Where changing a physical connection risks altering coupling, retain a reference branch so the operator can distinguish the expected difference from fixture movement. The experimental log needs actual transition timestamps rather than merely the order in which a script issued commands. A configuration change that has not settled is a third state, not an admissible sample of either adjacent steady state. Preserve transition intervals as excluded or separately analysed measurements.

Copyright 2026, James M. Atkinson

16.21 Nonlinear fingerprinting without circular source attribution

For a memoryless weak cubic response $y=a1\ x+a3\ x^3$ driven by two equal-frequency-separated sinusoids, the third-order product near one input frequency scales approximately with the cube of the input voltage while the corresponding small-signal fundamental scales linearly. Expressed in power decibels under fixed impedances and small-signal conditions, reducing both source tones by a common attenuation A dB reduces the third-order product approximately 3A dB and the fundamentals A dB. This familiar slope test is a hypothesis about a bounded transfer law. It is not valid through compression or automatic gain transitions, and it does not identify the physical circuit producing the nonlinearity unless source and combiner products have been independently bounded. A mixer, limiter, poor connector and test generator can all produce misleadingly similar slopes.

General nonlinear frequency formation is also not sufficient for source identification. An observed tone at $f_p=m\ f_1+n\ f_2$, with signed integer coefficients m and n, can be predicted from many input pairs, harmonics, images and frequency translations. Enumerate plausible combinations within the actual admitted input bands and establish whether the generators of the hypothesised terms were present. A local oscillator at f_{LO} can map an incoming signal to $f_{IF}=|f_{RF}-f_{LO}|$, but an image on the other side of the oscillator may yield the same magnitude. A clock harmonic may alias into the same digital bin. To separate these explanations, move the oscillator or sampling clock in a controlled way while keeping an independently identified external reference. The observed frequency shift

Copyright 2026, James M. Atkinson

must be compared with the signed prediction of each model and the applicable resolution uncertainty.

Receiver-origin attribution must survive a source-control test. Two RF signal generators that are insufficiently isolated can create intermodulation within their own output stages or combiner; a purported receiver spur is then already present at the input plane. Measure that plane with a suitably linear reference arrangement or separate the source paths with characterised isolation before accepting the nonlinear signature. Conversely, the absence of a product in a reference instrument proves little if its input filtering rejected the relevant frequency, if its sensitivity was inadequate, or if the particular transient occurred outside its valid observation interval. Every negative comparator must be qualified by matching frequency, time, noise, linearity and detector opportunity.

Copyright 2026, James M. Atkinson

16.22 Coupling paths that defeat the simple external-versus-internal dichotomy

Some observations arise from interaction between the building and the receiver rather than being either a freely radiated transmitter or a purely internal circuit error. Common-mode current on a coaxial cable can couple into an enclosure despite excellent differential shielding at the input connector. A powered USB lead, a network switch, an external reference cable, or a bias supply may convey structured interference into the digitiser or clock network. Moving the antenna can change the cable route, connector stress and common-mode impedance, so disappearance after relocation does not establish geometric localisation. A valid localisation trial measures or constrains those concomitant changes; ferrite and shield arrangements require their own frequency-dependent validation rather than being treated as magic suppression devices.

Mechanical coupling can produce microphonic phase or amplitude modulation in a resonator, cable, filter or oscillator. The visible trace may acquire spectral shoulders when a fan starts, a bench is touched, or vibration passes through a fixture. Instead of naming a specific component on the basis of correlation, perform a bounded mechanical or thermal challenge with a reference input whose physical RF characteristics are known. Record vibration or temperature synchronously with the raw RF stream. Distinguish a change in receiver transfer from a change in an actual radiating source, and avoid interventions that could damage hardware or move operation outside rated conditions. Thermal equilibration and

Copyright 2026, James M. Atkinson

connector torque belong to the measurement state if they materially affect the inference.

Copyright 2026, James M. Atkinson

16.23 Probabilistic evidence must preserve conditional assumptions

A likelihood ratio compares the probability of observed evidence E under two declared hypotheses, LR=P(E|H1)/P(E|H0). The computation is meaningful only when the probability models, nuisance variables and observation-selection process are specified. A report may use a likelihood-ratio framework to organise reasoning without assigning numerical probabilities when the necessary rates are unavailable. If a test is selected after an unusual peak appears, the conditioning on that selection is not optional. If two observations share the same sample data, clock, antenna path or analysis code, treating them as independent evidence multiplies support that has not been earned. An apparently precise ratio based on arbitrary priors or guessed false-alarm rates is inferior to an explicit statement that the mechanisms remain unresolved.

A negative survey finding is likewise a statement about a bounded event population and a demonstrated acquisition opportunity, not an unrestricted declaration of absence. Define C(f,t,s) as one for a time, frequency and receiver-state combination in which a stipulated event would have been observable with a validated criterion, and zero otherwise. This deterministic coverage indicator is not by itself a probability. A probability of missing an event requires a defensible model for when and where events occur and how the detector responds conditional on that opportunity. The report should separate unobserved frequency bands, settling intervals, missing samples, overload periods and threshold misses during valid acquisition.

Copyright 2026, James M. Atkinson

These gaps may affect different propositions and cannot be collapsed into a single unsupported percentage of confidence.

Copyright 2026, James M. Atkinson

16.24 Worked forensic adjudications with fully stipulated quantities

Case 16C.1. A controlled tone appears at -70.0 dBm before an input attenuation change and -80.2 dBm afterwards. The actual inserted loss, measured independently at the tone frequency, is 10.1 dB. The signed residual R=P_after-P_before+L is -0.1 dB. If the two level readings and loss calibration have independent standard uncertainties of 0.15, 0.15 and 0.10 dB, their combined standard uncertainty is sqrt(0.15^2+0.15^2+0.10^2)=0.2345 dB. The residual is compatible with zero under that model, but agreement does not establish that the component was external; a downstream gain correction or a correlated error could also produce agreement. Preserve raw readings, actual setting, covariance assumptions and source controls.

Case 16C.2. Two equal isolated input tones are each attenuated by 6 dB before a verified weak cubic receiver stage. A third-order component falls by 17.5 dB, with a combined measurement uncertainty of 0.7 dB. The ideal third-order prediction is an 18 dB decrease, whereas a linear external component predicts 6 dB under the same attenuation placement. The observation agrees with the cubic prediction within the stated uncertainty, but it does not distinguish receiver third-order response from upstream source or combiner nonlinearities unless those have been bounded independently. Repeating at two more levels and testing the product at the relevant input plane strengthens the mechanistic inference.

Case 16C.3. Four factorial observations of an explicitly defined detector-level statistic are y00=-90 dBm, y10=-100 dBm, y01=-75 dBm and y11=-93 dBm.

Copyright 2026, James M. Atkinson

The interaction contrast is -93-(-100)-(-75)+(-90)=-8 dB. A nonzero contrast indicates the effects of switching attenuation and gain are not additive in the chosen dBm response. It does not by itself specify compression, because the levels may reflect AGC response, changed bandwidth or source variation. The next experiment fixes the detector and bandwidth, monitors gain state and repeats an independently calibrated reference.

Case 16C.4. A putative external component persists in two receivers, but both share a reference oscillator that has a 20 MHz spur. A detector that derives its sample clock through the same multiplication chain can reproduce a related line in both systems. Treating the two observations as independent would overstate corroboration. A separate frequency reference and a controlled reference-switch test change the relevant error mechanism; the critical result is whether the candidate follows the clock-derived prediction while the external input and measurement opportunities remain equivalent.

Case 16C.5. A monitor records 30 hours, but 2 hours are invalid during calibration, 3 hours during retuning and 1 hour during known overload. If these exclusions are disjoint, valid recorded time is 24 hours, or 80 percent of elapsed time. The 80 percent is a verified time-coverage fraction, not an 80 percent probability of detecting an arbitrary transmitter. Such a probability would require the event-duration and start-time distribution, the observed frequencies and receiver sensitivity. If the excluded periods overlap, subtracting all six hours would itself be an error: compute the duration of their union.

Case 16C.6. Two independently measured bearings of 42 degrees and 47 degrees are obtained with estimated standard uncertainties of 3 and 4

Copyright 2026, James M. Atkinson

degrees, respectively. If errors are independent and small enough for local linear angular treatment, inverse-variance weighting yields (42/9+47/16)/(1/9+1/16)=43.8 degrees, with standard uncertainty sqrt(1/(1/9+1/16))=2.4 degrees. Shared antenna geometry, multipath or reference calibration invalidates the independence assumption and changes the result. This calculation does not show that a unique source exists, nor does a narrow angular interval establish ownership or intent.

Case 16C.7. A spectral candidate is present during a 10-second dwell while an independent monitor has a 1-second data gap overlapping that dwell. The monitor's negative exported trace cannot contradict the original observation unless the exact event window was actually acquired with adequate sensitivity. The correct comparison table records the candidate's earliest and latest physically supported occurrence, the comparator's valid sample-index intervals, and detector thresholds. File-creation timestamps are insufficient substitutes for acquisition epochs.

Case 16C.8. A hypothetical classifier labels 94 of 100 known calibration products correctly but has not been tested on novel external sources. The 94 percent accuracy pertains to the selected known-product population and says nothing about open-set false attribution. For a test of twenty independently selected new sources with no false labels, a one-sided binomial 95 percent upper false-label probability is 1-0.05^(1/20), approximately 13.9 percent, even under identical independent-trial assumptions. The result is too weak to support a universal identification assertion; explain population selection and independence before assigning quantitative confidence.

Copyright 2026, James M. Atkinson

Case 16C.9. A corrected input estimate is -88 dBm in a linear state. A second state gives -90 dBm, but its gain transition overlaps the event and the instantaneous response was not recorded. The difference is not a two-decibel environmental change measurement. Treat the first estimate as bounded by its calibration and the second as conditional or unusable for amplitude attribution until the transition response is recovered. Do not hide the uncertainty by averaging to -89 dBm.

Case 16C.10. A report has verified an RF component, an authorised device-state correlation and an independent directional constraint, but no unique evidence of a particular transmitter or individual. A defensible finding describes the signal, tested conditions and observed correlation, and states that source identification is unresolved. The case illustrates why a technically strong, bounded conclusion is more useful to a reviewing court or laboratory than an invented numerical probability of malicious purpose.

Copyright 2026, James M. Atkinson

16.25 An enforceable quality-release rule for the instrument and the report

Technical acceptance should be based on a matrix joining each permitted finding to its necessary evidence and validity checks. Detection requires a defined statistic and threshold over eligible acquisition intervals. Waveform classification adds calibrated signal-processing information and adversarial or out-of-class challenge tests. Physical localisation adds independently checked geometry, timing and propagation assumptions. Source attribution requires evidence that discriminates one candidate source from reasonable alternatives. A report should never promote a finding to a higher class simply because a more sophisticated receiver or algorithm was used. Each class has a failure state: nonreproducible observations, missing configuration, calibration inconsistency, clipping, unknown reference behaviour, or an untested alternative explanation.

Release of the receiver configuration is a separate proposition from release of a case conclusion. A receiver may pass a laboratory acceptance test and later operate in an invalid field state; conversely, a particular observation may be reproducible even if another function of the instrument is defective. Preserve asset identity, firmware and FPGA versions, preselector response, gain limits, clock distribution, software processing, calibration revisions and relevant environmental conditions as a controlled configuration. After repairs, firmware changes or suspected overload, rerun the tests that exercise affected functions. The continuous record should identify intervals for which the asserted validity is supported, the specific tests used and any

Copyright 2026, James M. Atkinson

untested mechanisms. A passed self-test is evidence about the self-test, not proof of every measurement performed in the preceding engagement.

Copyright 2026, James M. Atkinson

16.26 Interpreting extracted I/Q features without confusing waveform identity, source identity and transmitted information

The evidential chain starts at the declared input plane. An observed transient must be associated with a receiver slice whose gain, phase, clock, bandwidth and overload state were valid at the sample times. The next inference is that a signal-like structure was present in the retained complex measurements; a further inference may classify modulation family or emission behaviour. Identifying the physical emitter requires additional independent evidence, such as antenna bearing, controlled equipment-state changes or corroboration under a differently configured receiver. Identifying the owner, authorised use, intended purpose or information content is a distinct legal and evidential problem. Treating a cyclostationary feature, an I/Q constellation or a protocol-shaped packet as proof of a particular device collapses those inference levels without justification.

A robust artifact test varies the measurement chain while retaining the observation capability. An image at a mirrored complex frequency which changes when I/Q gain imbalance is corrected may be a conversion artifact rather than a second source. A narrow line which moves when the ADC sample clock changes may be a sampling spur. A frequency component that appears only when a high-gain front end is connected may arise from receiver compression, but external signals can also respond to changed detection thresholds. A second receiver's nondetection is discriminating only if it had comparable relevant frequency coverage, timing opportunity, sensitivity and gain validity. Preserve predicted changes for each hypothesis

Copyright 2026, James M. Atkinson

before looking at the outcome; post hoc storytelling can make almost any trace appear consistent with a preferred mechanism.

For a large parallel system, common-mode artifacts can defeat apparent multiplicity. Four hundred simultaneous receive channels do not constitute four hundred independent confirmations when they share one defective reference, one network clock, common power supply, contaminated calibration injection, flawed sign convention or common GPU spectral transform. Review the graph of shared dependencies and seek a test that breaks the suspected common cause. A candidate line appearing simultaneously in many channels can be powerful evidence of a common error rather than proof of a wideband source. Correlation should be calculated with timestamps and appropriate channel noise covariance; a coloured spectrogram is an illustration, not an inferential model.

The retention rule is as important as the classifier. A four-hour archive of peak lists but no raw samples may preserve valuable spectral occupancy evidence, but it generally cannot support later re-estimation of pulse phase code or recovery of a transient suppressed by the original detector. An event-triggered archive may preserve just the right I/Q segments, yet an absent segment cannot exclude an event which the trigger was not designed to recognise. Therefore record a per-band, per-time coverage ledger, detector thresholds and revisions, sample gaps, ring-buffer deadlines, known tests and rejected candidates. A negative conclusion must specify the event class and tested capability rather than claiming the RF environment was empty.

Scientific reconstruction requires versioned transformations from raw I/Q through channel selection, demodulation, feature extraction, classification

and any lawful content interpretation. The processing graph should retain original hashes, each output's source-sample interval, software version, coefficients, RF-to-baseband mapping and uncertainty. A new algorithm can legitimately identify a waveform previously missed within saved samples, but it cannot retroactively acquire waveforms that were never stored. Independent replication should include at least one receiver or recording whose significant hardware, clock or processing error paths differ from the original. When source identity remains unresolved, report the measurements and surviving hypotheses with precision rather than extending the result into unsupported attribution.

Chapter Summary

Receiver conclusions are earned through architecture-based challenge tests, independent evidence, explicit finding categories, and lifecycle control. The strongest result is not the most dramatic trace but the one that survives changes to the measurement chain and competing explanations.

Begin with mechanisms located in the measurement architecture and write competing predictions before changing controls. Preserve desired observation capability through each comparison. A disappearance can reflect changed sensitivity, coupling or state, and agreement between two receivers can retain shared errors. The model families provide conditional predictions; no single signature establishes attribution.

Cross relevant control settings when their combinations are physically meaningful. Define the response consistently, retain fresh acquisitions and run order, and distinguish settled behavior from transitions. Replication, randomization and blocking address different design questions. An interaction narrows the explanatory problem while leaving component identity and mechanism to further discriminating evidence.

Report the category and limit actually supported: detection, classification, localization, linkage or an unresolved observation. Reconcile cross-domain timing and common dependencies instead of manufacturing independent evidence or numerical odds. Preserve failed tests and native records for review. After hardware, software or correction changes, regression checks maintain the specific accepted functions and explain any revised result without changing the underlying observation.

Chapter 16 Assessments

This section contains 250 items: 100 multiple-choice, 100 fill-in-the-blank, 25 essay and 25 discussion. Choose one best answer for each multiple-choice item. Supply the requested technical term, quantity or condition for each blank. For essay and discussion responses, explain the governing mechanism, assumptions, evidence and limits of the claim. Numerical assessment cases use hypothetical inputs unless an item explicitly identifies a published source. Retain units and distinguish power, voltage and logarithmic quantities. Answers, rationales and response guidance follow the complete question set; their review links lead to the supporting text.

Multiple-Choice Questions

V011-C16-MCQ-001. What makes a receiver challenge discriminating?

A. The intervention always removes the feature

B. The operator prefers one explanation before testing

C. The changed control has an intuitive label

D. Competing mechanisms predict different outcomes while relevant observation capability is preserved

Answer: D. Predictions and controlled capability turn a change into a meaningful mechanism comparison. Source: §16.2 Challenge-Test Design (p. 9258)

Why the selected alternative fits: Competing mechanisms predict different outcomes while relevant observation capability is preserved.

Distinguishing consideration: compare this with option A, “The intervention always removes the feature”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Challenge-Test Design.

Review: Chapter 16 — Challenge-Test Design.

V011-C16-MCQ-002. Does corrected attenuation scaling alone prove an external emitter?

A. Yes; all internal emissions ignore attenuation

B. No; attenuation tests never provide useful evidence

C. No; instrument emission coupled through the input path can scale similarly

D. Yes; agreement within uncertainty proves authorization

Answer: C. The result supports a bounded transfer compatibility, not unique source attribution. Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

Why the selected alternative fits: No; instrument emission coupled through the input path can scale similarly.

Distinguishing consideration: compare this with option A, “Yes; all internal emissions ignore attenuation”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-MCQ-003. Why not derive numerical likelihoods from a count of favorable challenge tests?

A. Every test result has equal likelihood by definition

B. An expert confidence label supplies the missing probabilities

C. Valid models for hypotheses, data, dependence and selection are required

D. Different test names guarantee statistical independence

Answer: C. Equation 32 defines a model-based ratio, not an arbitrary evidence score. Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

Why the selected alternative fits: Valid models for hypotheses, data, dependence and selection are required.

Distinguishing consideration: compare this with option A, “Every test result has equal likelihood by definition”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-MCQ-004. What must a regression release preserve?

A. Only a passing startup self-test

B. Prior and changed configurations, reference checks, processing identity and unresolved limits

C. Only the revised conclusion without the original derivation

D. Only the latest corrected chart

Answer: B. Native observations and both processing states make revisions reviewable. Source: §16.15 Close the receiver method through configuration-specific regression (p. 9287)

Why the selected alternative fits: Prior and changed configurations, reference checks, processing identity and unresolved limits.

Distinguishing consideration: compare this with option A, “Only a passing startup self-test”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Close the receiver method through configuration-specific regression.

Review: Chapter 16 — Close the receiver method through configuration-specific regression.

V011-C16-MCQ-005. Why can a successful one-control challenge leave a mechanism unresolved?

A. Changing one menu option guarantees one physical cause changed

B. Its effect can depend on another fixed control setting

C. One-control tests are always mathematically invalid

D. Any disappearance proves that control is defective

Answer: B. Relevant combinations may reveal interaction outside the original comparison. Source: §16.4 Receiver challenges with interacting controls (p. 9262)

Why the selected alternative fits: Its effect can depend on another fixed control setting.

Distinguishing consideration: compare this with option A, “Changing one menu option guarantees one physical cause changed”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Receiver challenges with interacting controls.

Review: Chapter 16 — Receiver challenges with interacting controls.

V011-C16-MCQ-006. A line appears only with the original reference and switch in circuit, with comparable capability in all four states. What follows immediately?

A. The response is associated with that tested joint configuration

B. Both components independently generate the line

C. The switch alone is proved defective

D. The line is physically absent at every level in the other states

Answer: A. The pattern motivates shared-path tests but does not uniquely locate the source. Source: §16.4.3 Interpret hypothetical receiver records (p. 9268)

Why the selected alternative fits: The response is associated with that tested joint configuration.

Distinguishing consideration: compare this with option B, “Both components independently generate the line”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Interpret hypothetical receiver records.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-MCQ-007. Why is a passing continuous-tone check insufficient for every negative burst observation?

A. Burst detectability is independent of acquisition timing

B. It may leave trigger, settling, dead time and continuity untested

C. A continuous tone cannot test any amplitude transfer

D. Tone agreement proves every waveform class has equal sensitivity

Answer: B. The reference should exercise the capability supporting the negative claim. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why the selected alternative fits: It may leave trigger, settling, dead time and continuity untested.

Distinguishing consideration: compare this with option A, “Burst detectability is independent of acquisition timing”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

V011-C16-MCQ-008. How should an unexplained initial line be classified before challenges?

A. As a receiver artifact solely because artifacts exist

B. As an unexplained observation with competing mechanisms

C. As an unauthorized transmitter by default

D. As a confirmed surveillance function if modulation is recognizable

Answer: B. Classification should follow evidence rather than the drama of the trace.

Source: §16.1 Artifact Taxonomy and Competing Explanations (p. 9257)

Why the selected alternative fits: As an unexplained observation with competing mechanisms.

Distinguishing consideration: compare this with option A, “As a receiver artifact solely because artifacts exist”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Artifact Taxonomy and Competing Explanations.

Review: Chapter 16 — Artifact Taxonomy and Competing Explanations.

V011-C16-MCQ-009. Why begin artifact analysis with an architecture map?

A. Component labels alone identify all causal paths

B. Controls act differently on mechanisms before and after their location

C. Every artifact originates in the final detector

D. The map supplies numerical likelihoods automatically

Answer: B. Stage placement gives conditional predictions for interventions. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why the selected alternative fits: Controls act differently on mechanisms before and after their location.

Distinguishing consideration: compare this with option A, “Component labels alone identify all causal paths”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Localize an artifact by changing the stage that could create it.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

V011-C16-MCQ-010. Which change directly challenges an alias hypothesis when interpreted with the actual mapping?

A. Only changing the plot color scale

B. A controlled sample-rate change

C. Only increasing post-detection averaging at unchanged rate

D. Only relabeling the center frequency

Answer: B. An alias should follow the sampling map, while other mechanisms may behave differently. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why the selected alternative fits: A controlled sample-rate change.

Distinguishing consideration: compare this with option A, “Only changing the plot color scale”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Localize an artifact by changing the stage that could create it.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

V011-C16-MCQ-011. Which evidence helps distinguish a conversion image?

A. A large file with no frequency metadata

B. A stable displayed label under an unknown LO state

C. A single antenna certificate

D. Movement under a declared conversion plan or image-selective preselection

Answer: D. The signed conversion model predicts candidate movement and admission. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why the selected alternative fits: Movement under a declared conversion plan or image-selective preselection.

Distinguishing consideration: compare this with option A, “A large file with no frequency metadata”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Localize an artifact by changing the stage that could create it.

V011-C16-MCQ-012. Where should attenuation be changed to test generation in a proposed nonlinear stage?

A. Before that stage, with parent levels and desired transfer controlled

B. Anywhere, because attenuation location never matters

C. At an unrelated output that never reaches the stage

D. Only after the final display detector

Answer: A. Products generated after the changed input can scale differently from an already present signal. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why the selected alternative fits: Before that stage, with parent levels and desired transfer controlled.

Distinguishing consideration: compare this with option B, “Anywhere, because attenuation location never matters”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Localize an artifact by changing the stage that could create it.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-013. What can a preamplifier bypass test discriminate when capability is preserved?

A. Every possible cause uniquely from one disappearance

B. A response generated in or dependent on that active path versus one already at its input

C. The absolute time of an external event without clock information

D. The source's authorization status

Answer: B. Bypass changes the architecture, but its gain and sensitivity effects must be accounted for. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why the selected alternative fits: A response generated in or dependent on that active path versus one already at its input.

Distinguishing consideration: compare this with option A, “Every possible cause uniquely from one disappearance”; that competing statement does not meet the question’s stated requirement.

V011-C16-MCQ-014. Why write predictions for at least two explanations before the intervention?

A. To guarantee one prediction will be correct

B. To turn every observed difference into causation

C. To avoid recording unexpected outcomes

D. To define what the test could distinguish and reduce post hoc interpretation

Answer: D. Predeclared alternatives give the test a reviewable purpose. Source: §16.2 Challenge-Test Design (p. 9258)

Why the selected alternative fits: To define what the test could distinguish and reduce post hoc interpretation.

Distinguishing consideration: compare this with option A, "To guarantee one prediction will be correct"; that competing statement does not meet the question's stated requirement.

Basis and limitation: Chapter 16 — Challenge-Test Design.

Review: Chapter 16 — Challenge-Test Design.

V011-C16-MCQ-016. What is a limitation of receiver substitution using a shared antenna, clock and software?

A. Two receivers necessarily provide independent confirmation

B. Shared resources guarantee both instruments are correct

C. Substitution eliminates all coupling paths automatically

D. The original cause can persist through shared dependencies

Answer: D. An informative substitution should change relevant error structure.

Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why the selected alternative fits: The original cause can persist through shared dependencies.

Distinguishing consideration: compare this with option A, “Two receivers necessarily provide independent confirmation”; that competing statement does not meet the question’s stated requirement.

V011-C16-MCQ-017. Why carry a known reference through both substitute receivers?

A. To identify the external emitter directly

B. To interpret nondetection against demonstrated capability

C. To eliminate the need for state-specific corrections

D. To prove all internal errors are independent

Answer: B. A less sensitive path can hide a real feature. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why the selected alternative fits: To interpret nondetection against demonstrated capability.

Distinguishing consideration: compare this with option A, “To identify the external emitter directly”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Localize an artifact by changing the stage that could create it.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-019. Why is a plausible decoded identifier insufficient for attribution?

A. Modulation cannot carry identifiers

B. A decoder output automatically proves physical device linkage

C. It may be stale, repeated or a false lock

D. Every decoded identifier is necessarily false

Answer: C. Waveform interpretation needs validation and linkage evidence. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why the selected alternative fits: It may be stale, repeated or a false lock.

Distinguishing consideration: compare this with option A, “Modulation cannot carry identifiers”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Localize an artifact by changing the stage that could create it.

V011-C16-MCQ-034. Why might a wideband modulated reference be preferable to a narrow tone?

A. It removes all calibration uncertainty

B. It always has lower distortion than a tone

C. The comparison concerns wideband modulation performance

D. It automatically establishes every trigger condition

Answer: C. Reference choice follows the function being compared. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why the selected alternative fits: The comparison concerns wideband modulation performance.

Distinguishing consideration: compare this with option A, “It removes all calibration uncertainty”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

V011-C16-MCQ-035. When a bypass cable changes the reference plane, what is needed?

A. A relabeling with no measurement change

B. Applicable path correction and uncertainty or a narrower quantitative claim

C. An assumption that all bypasses are transparent

D. Only the same nominal connector type

Answer: B. Comparisons must refer to the same supported measurand. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why the selected alternative fits: Applicable path correction and uncertainty or a narrower quantitative claim.

Distinguishing consideration: compare this with option A, “A relabeling with no measurement change”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

V011-C16-MCQ-036. A state lacks necessary characterization but yields a visible feature. What can be retained?

A. An automatic rejection of all data in every other state

B. A zero uncertainty because the feature is visible

C. The observation with limited quantitative comparability

D. A fully calibrated difference by association

Answer: C. Incomplete characterization limits the claim rather than erasing the observation. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why the selected alternative fits: The observation with limited quantitative comparability.

Distinguishing consideration: compare this with option A, “An automatic rejection of all data in every other state”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

V011-C16-MCQ-037. Why separate settled-state records from transition records?

A. Settled behavior proves all transitions harmless

B. Every observed burst is a steady-state signal

C. Relocking, impulses and recovery history can change the mechanism

D. Transitions are always invalid and should be deleted

Answer: C. A transition-only phenomenon may deserve its own dedicated comparison. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why the selected alternative fits: Relocking, impulses and recovery history can change the mechanism.

Distinguishing consideration: compare this with option A, “Settled behavior proves all transitions harmless”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-038. What should happen to transition data excluded from a settled analysis?

A. Assume they contain no useful mechanism information

B. Preserve them with the exclusion reason

C. Relabel them as settled if the final plot looks smooth

D. Erase them to simplify the record

Answer: B. Exclusion from one estimator should not destroy the evidence. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why the selected alternative fits: Preserve them with the exclusion reason.

Distinguishing consideration: compare this with option A, “Assume they contain no useful mechanism information”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

V011-C16-MCQ-039. In the hypothetical clock/switch pattern, what should repeated returns to the original combination test?

A. Whether the response reproduces under that state

B. Whether every other configuration has zero physical power

C. Whether both factors are independent causes by definition

D. Whether the factor labels are unchanged

Answer: A. Fresh reversals strengthen the state-association record while retaining limits. Source: §16.4.3 Interpret hypothetical receiver records (p. 9268)

Why the selected alternative fits: Whether the response reproduces under that state.

Distinguishing consideration: compare this with option B, “Whether every other configuration has zero physical power”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Interpret hypothetical receiver records.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-MCQ-040. What qualifies a conclusion that a line is absent in the other three states?

A. A proof that the source no longer exists

B. Universal absence at every possible level

C. The declared criterion and demonstrated observation limits

D. Absence in every untested frequency band

Answer: C. Nondetection is bounded by capability and exposure. Source: §16.4.3 Interpret hypothetical receiver records (p. 9268)

Why the selected alternative fits: The declared criterion and demonstrated observation limits.

Distinguishing consideration: compare this with option A, “A proof that the source no longer exists”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Interpret hypothetical receiver records.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-MCQ-041. A spur appears only with high gain and broadband admission. Which hypothesis is compatible?

A. Loading requiring admitted strong parents and sufficient downstream gain

B. A proved external transmitter unaffected by the receiver

C. A universal rule that high gain generates every spur

D. A proved defect in the input filter alone

Answer: A. Parent levels, source purity, mismatch and control behavior still require checks. Source: §16.4.3 Interpret hypothetical receiver records (p. 9268)

Why the selected alternative fits: Loading requiring admitted strong parents and sufficient downstream gain.

Distinguishing consideration: compare this with option B, “A proved external transmitter unaffected by the receiver”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Interpret hypothetical receiver records.

Review: Chapter 16 — Interpret hypothetical receiver records.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-042. Why not attribute that spur immediately to one nonlinear stage?

A. A four-state design cannot reveal any dependence

B. The receiver's gain setting has no physical effect

C. Sources, combiners, mismatch or gain-control changes can mimic the pattern

D. Nonlinear products never respond to preselection

Answer: C. The pattern is informative but not stage-unique. Source: §16.4.3 Interpret hypothetical receiver records (p. 9268)

Why the selected alternative fits: Sources, combiners, mismatch or gain-control changes can mimic the pattern.

Distinguishing consideration: compare this with option A, “A four-state design cannot reveal any dependence”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Interpret hypothetical receiver records.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-MCQ-043. A stricter decoder rule removes field identifiers while valid reference records survive. What additional comparison is useful?

A. An independently acquired noise-only record processed under both rules

B. An assumption that stricter always means correct

C. Only the original field record re-plotted

D. A new identifier selected from the same training events

Answer: A. The crossed input/rule comparison tests false-lock behavior under that noise condition. Source: §16.4.3 Interpret hypothetical receiver records (p. 9268)

Why the selected alternative fits: An independently acquired noise-only record processed under both rules.

Distinguishing consideration: compare this with option B, “An assumption that stricter always means correct”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Interpret hypothetical receiver records.

Review: Chapter 16 — Interpret hypothetical receiver records.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-044. If the stricter rule was chosen using the same suspicious events, what is needed for broader validation?

A. More overlapping windows from the same fitted events alone

B. A higher confidence label

C. A guarantee that all future events share the training distribution

D. An independently retained validation record

Answer: D. Fitted examples do not establish held-out performance. Source: §16.4.3 Interpret hypothetical receiver records (p. 9268)

Why the selected alternative fits: An independently retained validation record.

Distinguishing consideration: compare this with option A, “More overlapping windows from the same fitted events alone”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Interpret hypothetical receiver records.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-MCQ-045. What is genuine replication of a receiver intervention?

A. Fresh acquisitions revisiting the physical configuration

B. Replotting the same capture at another scale

C. Exporting the same spectrum twice

D. Dividing one record into overlapping windows only

Answer: A. Replication should revisit the experimental state and its variability.

Source: §16.4.4 Record repetition and the limits of the design (p. 9270)

Why the selected alternative fits: Fresh acquisitions revisiting the physical configuration.

Distinguishing consideration: compare this with option B, “Replotting the same capture at another scale”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Record repetition and the limits of the design.

Review: Chapter 16 — Record repetition and the limits of the design.

V011-C16-MCQ-046. Why randomize run order when feasible?

A. To make every physical error disappear

B. To substitute for calibration

C. To establish Gaussian noise automatically

D. To reduce systematic association between setting and extraneous temporal changes

Answer: D. Order control addresses drift and confounding, not all validity conditions. Source: §16.4.4 Record repetition and the limits of the design (p. 9270)

Why the selected alternative fits: To reduce systematic association between setting and extraneous temporal changes.

Distinguishing consideration: compare this with option A, “To make every physical error disappear”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Record repetition and the limits of the design.

Review: Chapter 16 — Record repetition and the limits of the design.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-047. When relocking or access constrains run order, what should be done?

A. Discard all timing information

B. Assume the constraint creates independence

C. Document the restriction and corresponding limitation

D. Describe the order as randomized anyway

Answer: C. The actual design must remain visible. Source: §16.4.4 Record repetition and the limits of the design (p. 9270)

Why the selected alternative fits: Document the restriction and corresponding limitation.

Distinguishing consideration: compare this with option A, “Discard all timing information”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Record repetition and the limits of the design.

Review: Chapter 16 — Record repetition and the limits of the design.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-048. What is blocking in the chapter's design discussion?

A. A synonym for independent replication

B. Removing the nuisance condition from physical reality

C. Grouping comparisons under a declared nuisance condition

D. Preventing every unwanted RF signal

Answer: C. Within-group comparisons can control a condition while retaining group membership. Source: §16.4.4 Record repetition and the limits of the design (p. 9270)

Why the selected alternative fits: Grouping comparisons under a declared nuisance condition.

Distinguishing consideration: compare this with option A, “A synonym for independent replication”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Record repetition and the limits of the design.

Review: Chapter 16 — Record repetition and the limits of the design.

V011-C16-MCQ-049. All original-reference observations occur in session 1 and alternate-reference observations in session 2. What is confounded?

A. Reference state and session

B. Only the displayed frequency units

C. The two receivers' serial-number syntax

D. Every within-session measurement independently

Answer: A. More repetitions inside each session cannot supply missing crossed comparisons. Source: §16.4.4 Record repetition and the limits of the design (p. 9270)

Why the selected alternative fits: Reference state and session.

Distinguishing consideration: compare this with option B, “Only the displayed frequency units”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Record repetition and the limits of the design.

Review: Chapter 16 — Record repetition and the limits of the design.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-050. How can that session/reference ambiguity be resolved when feasible?

A. Acquire meaningful missing combinations across sessions or report the limit

B. Assign the full difference to reference state

C. Remove session labels from the dataset

D. Average each session more and assume the confound vanishes

Answer: A. The design needs the missing causal contrast. Source: §16.4.4 Record repetition and the limits of the design (p. 9270)

Why the selected alternative fits: Acquire meaningful missing combinations across sessions or report the limit.

Distinguishing consideration: compare this with option B, “Assign the full difference to reference state”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Record repetition and the limits of the design.

Review: Chapter 16 — Record repetition and the limits of the design.

V011-C16-MCQ-052. Why can cross-domain agreement fail to be independent?

A. Different sensor types are always independent

B. Optical observations automatically validate RF source identity

C. Only RF sensors can share errors

D. Sensors may share power, clocks, cables, software or environmental causes

Answer: D. Common dependencies can preserve one cause across apparently different channels. Source: §16.5 Integration with Direction, Wireline, Optical, and Physical Evidence (p. 9274)

Why the selected alternative fits: Sensors may share power, clocks, cables, software or environmental causes.

Distinguishing consideration: compare this with option A, “Different sensor types are always independent”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Integration with Direction, Wireline, Optical, and Physical Evidence.

V011-C16-MCQ-053. What makes a new modality particularly valuable?

A. It changes the relevant error structure while observing the needed question

B. It repeats the same decoder on identical samples

C. It shares every timing and coupling path

D. It has a different product label alone

Answer: A. Independent mechanisms of observation strengthen discrimination.

Source: §16.5 Integration with Direction, Wireline, Optical, and Physical Evidence (p. 9274)

Why the selected alternative fits: It changes the relevant error structure while observing the needed question.

Distinguishing consideration: compare this with option B, “It repeats the same decoder on identical samples”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Integration with Direction, Wireline, Optical, and Physical Evidence.

V011-C16-MCQ-054. Why reconcile time bases when combining receiver and physical-event records?

A. Equal displayed seconds guarantee simultaneity

B. A physical sensor has no timing uncertainty

C. Temporal agreement depends on clock relation and uncertainty

D. Any simultaneous-looking plot proves causation

Answer: C. State and time alignment are prerequisites for cross-domain inference.

Source: §16.5 Integration with Direction, Wireline, Optical, and Physical Evidence (p. 9274)

Why the selected alternative fits: Temporal agreement depends on clock relation and uncertainty.

Distinguishing consideration: compare this with option A, “Equal displayed seconds guarantee simultaneity”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Integration with Direction, Wireline, Optical, and Physical Evidence.

V011-C16-MCQ-057. Which elements are needed beyond frequency and modulation for confirmed technical-surveillance function?

A. Physical or operational linkage, information path, authorization, reproducibility and continuity

B. Only two receivers seeing a line

C. Only a plausible decoded identifier

D. Only strong signal power

Answer: A. Functional attribution is a stronger claim than waveform classification.

Source: §16.6 Findings, Reports, and Decision Ladders (p. 9275)

Why the selected alternative fits: Physical or operational linkage, information path, authorization, reproducibility and continuity.

Distinguishing consideration: compare this with option B, “Only two receivers seeing a line”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Findings, Reports, and Decision Ladders.

V011-C16-MCQ-071. What does a noise-only decoder control test directly?

A. The origin of every field decode

B. The authorization of a signal

C. Detector behavior under that retained noise condition and processing rule

D. Universal false-alarm performance under all noise laws

Answer: C. Its scope is specific and should not be generalized without evidence.

Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

Why the selected alternative fits: Detector behavior under that retained noise condition and processing rule.

Distinguishing consideration: compare this with option A, “The origin of every field decode”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-MCQ-072. Why retain failed as well as passed controls?

A. Only passes affect validity

B. Failures can limit earlier conclusions and reveal state dependence

C. They can be replaced by an average confidence score

D. Failed controls become irrelevant after one successful repeat

Answer: B. The evidence record should preserve unfavorable outcomes. Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

Why the selected alternative fits: Failures can limit earlier conclusions and reveal state dependence.

Distinguishing consideration: compare this with option A, “Only passes affect validity”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-MCQ-073. What should a technical finding explicitly distinguish?

A. Detection, classification, correlation, localization and device linkage

B. Only old versus new instruments

C. All inference categories as equivalent

D. Only strong versus weak display levels

Answer: A. Each claim requires different evidence. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

Why the selected alternative fits: Detection, classification, correlation, localization and device linkage.

Distinguishing consideration: compare this with option B, “Only old versus new instruments”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Write findings that preserve the strength and limit of each test.

Review: Chapter 16 — Write findings that preserve the strength and limit of each test.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-074. Why put units, bandwidth, normalization, planes and uncertainty beside derived values?

A. To prove the chosen mechanism

B. To replace native samples

C. To preserve their meaning outside the original instrument session

D. To make all values directly comparable without further checks

Answer: C. A bare number loses its measurement definition. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

Why the selected alternative fits: To preserve their meaning outside the original instrument session.

Distinguishing consideration: compare this with option A, “To prove the chosen mechanism”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Write findings that preserve the strength and limit of each test.

Review: Chapter 16 — Write findings that preserve the strength and limit of each test.

V011-C16-MCQ-075. What makes a follow-up test more informative than repeating unchanged settings?

A. It necessarily raises the signal level

B. It produces more visually attractive data

C. It avoids recording calibration

D. It discriminates remaining mechanisms by changing a relevant path or state

Answer: D. Repeatability and causal discrimination are different objectives. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

Why the selected alternative fits: It discriminates remaining mechanisms by changing a relevant path or state.

Distinguishing consideration: compare this with option A, "It necessarily raises the signal level"; that competing statement does not meet the question's stated requirement.

Basis and limitation: Chapter 16 — Write findings that preserve the strength and limit of each test.

Review: Chapter 16 — Write findings that preserve the strength and limit of each test.

V011-C16-MCQ-076. When a proposed discriminating test is not performed, what should be recorded?

A. An assumed favorable outcome

B. Why it was omitted and how that limits the conclusion

C. A declaration that the omission is irrelevant

D. Only tests that were convenient

Answer: B. Missing evidence should remain visible. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

Why the selected alternative fits: Why it was omitted and how that limits the conclusion.

Distinguishing consideration: compare this with option A, “An assumed favorable outcome”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Write findings that preserve the strength and limit of each test.

Review: Chapter 16 — Write findings that preserve the strength and limit of each test.

V011-C16-MCQ-077. What belongs in a reusable established-artifact record?

A. A universal condemnation of the instrument class

B. Exhibiting configurations, stimulus/state, predicted and observed response, challenge and mitigation

C. Only a source attribution label

D. Only the final corrected spectrum

Answer: B. The record should let another examiner reproduce and test applicability.

Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

Why the selected alternative fits: Exhibiting configurations, stimulus/state, predicted and observed response, challenge and mitigation.

Distinguishing consideration: compare this with option A, “A universal condemnation of the instrument class”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Write findings that preserve the strength and limit of each test.

Review: Chapter 16 — Write findings that preserve the strength and limit of each test.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-078. Why not turn one artifact incident into a universal receiver rule?

A. No receiver model can be useful

B. Every future instrument has identical coupling

C. The mechanism was established only within tested conditions

D. Artifacts never repeat

Answer: C. A narrow controlled result should retain its domain. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

Why the selected alternative fits: The mechanism was established only within tested conditions.

Distinguishing consideration: compare this with option A, “No receiver model can be useful”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Write findings that preserve the strength and limit of each test.

Review: Chapter 16 — Write findings that preserve the strength and limit of each test.

V011-C16-MCQ-079. Which change can warrant acceptance or regression testing?

A. Only purchasing a new receiver

B. Only changing the room's report name

C. Repair, firmware, accessory, calibration or major software change

D. Only replacing the antenna manufacturer logo

Answer: C. Changes can affect several measurement functions. Source: §16.9 Acceptance, Maintenance, and Lifecycle Control (p. 9280)

Why the selected alternative fits: Repair, firmware, accessory, calibration or major software change.

Distinguishing consideration: compare this with option A, “Only purchasing a new receiver”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Acceptance, Maintenance, and Lifecycle Control.

Review: Chapter 16 — Acceptance, Maintenance, and Lifecycle Control.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-080. Why is a center-frequency calibration tone insufficient for full-chain acceptance?

A. It proves all modulation performance automatically

B. It leaves many noise, dynamic-range, image, timing, trigger and continuity functions untested

C. It replaces the need for sample metadata

D. It cannot verify any frequency or amplitude behavior

Answer: B. Acceptance must cover the deployed method's actual functions. Source: §16.9 Acceptance, Maintenance, and Lifecycle Control (p. 9280)

Why the selected alternative fits: It leaves many noise, dynamic-range, image, timing, trigger and continuity functions untested.

Distinguishing consideration: compare this with option A, “It proves all modulation performance automatically”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Acceptance, Maintenance, and Lifecycle Control.

Review: Chapter 16 — Acceptance, Maintenance, and Lifecycle Control.

V011-C16-MCQ-085. For raw levels −83.0 and −93.2 dBm with 10.0 dB added attenuation on the second, what is corrected second level?

A. −93.2 dBm

B. −73.2 dBm

C. −83.2 dBm

D. −103.2 dBm

Answer: C. Refer the second reading upstream by adding the attenuation. Source: §16.12 Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance (p. 9284)

Why the selected alternative fits: −83.2 dBm.

Distinguishing consideration: compare this with option A, "−93.2 dBm"; that competing statement does not meet the question's stated requirement.

Basis and limitation: Chapter 16 — Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

Review: Chapter 16 — Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-086. For corrected levels P1,corr=−83.0 dBm and P2,corr=−83.2 dBm, what is signed eA=P2,corr−P1,corr?

A. +10.0 dB

B. +0.2 dB

C. −10.2 dB

D. −0.2 dB

Answer: D. −83.2−(−83.0)=−0.2 dB. Source: §16.12 Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance (p. 9284)

Why the selected alternative fits: −0.2 dB.

Distinguishing consideration: compare this with option A, “+10.0 dB”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

Review: Chapter 16 — Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-087. For corrected levels −83.0 and −83.2 dBm with 0.7 dB combined comparison uncertainty, what interpretation is supported?

A. The 0.2 dB magnitude is compatible with corrected scaling at that resolution

B. Both corrected levels are exactly equal

C. The source is uniquely external and unauthorized

D. The receiver is proved artifact-free at every state

Answer: A. The test does not establish source or authorization. Source: §16.12 Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance (p. 9284)

Why the selected alternative fits: The 0.2 dB magnitude is compatible with corrected scaling at that resolution.

Distinguishing consideration: compare this with option B, “Both corrected levels are exactly equal”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

Review: Chapter 16 — Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

V011-C16-MCQ-088. In the keyboard/clock/switch case, why is removing the line after a joint intervention incomplete attribution evidence?

A. The disappearance proves both components independently emit

B. Two conditions changed and capability plus separate effects remain to be checked

C. LED activity proves the removed RF line's source

D. A joint change is never informative at all

Answer: B. Separate reference/switch challenges, reversals and suitable-reference checks are needed. Source: §16.13 Hypothetical Case Adjudication: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance (p. 9285)

Why the selected alternative fits: Two conditions changed and capability plus separate effects remain to be checked.

Distinguishing consideration: compare this with option A, “The disappearance proves both components independently emit”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Hypothetical Case Adjudication: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

Review: Chapter 16 — Hypothetical Case Adjudication: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

V011-C16-MCQ-089. What does the release gate require when a result disappears under a challenge?

A. Delete the original trace

B. Assign a universal artifact category without capability checks

C. Resolve the mechanism sufficiently for the proposed attribution while preserving data and alternatives

D. Declare the original observation false automatically

Answer: C. Disappearance can reflect sensitivity or route changes. Source: §16.14 Challenge-Test and Evidence Release Gate (p. 9286)

Why the selected alternative fits: Resolve the mechanism sufficiently for the proposed attribution while preserving data and alternatives.

Distinguishing consideration: compare this with option A, “Delete the original trace”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Challenge-Test and Evidence Release Gate.

Review: Chapter 16 — Challenge-Test and Evidence Release Gate.

V011-C16-MCQ-090. How should old and changed configurations be treated during regression?

A. As interchangeable once the new software launches

B. As identical if the hardware serial is unchanged

C. As one averaged state to reduce paperwork

D. As distinct states until relevant comparisons are complete

Answer: D. The accepted domain must be established for the new configuration.

Source: §16.15 Close the receiver method through configuration-specific regression (p. 9287)

Why the selected alternative fits: As distinct states until relevant comparisons are complete.

Distinguishing consideration: compare this with option A, “As interchangeable once the new software launches”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Close the receiver method through configuration-specific regression.

Review: Chapter 16 — Close the receiver method through configuration-specific regression.

Copyright 2026, James M. Atkinson

V011-C16-MCQ-091. A new processing correction changes reported results from retained samples. What should be preserved?

A. A modified native file made to match the new conclusion

B. Both derived versions with processing identities and an explanation of the difference

C. Only the correction's filename

D. Only the new output, with old labels reused

Answer: B. The underlying observation and revised derivation must remain distinguishable. Source: §16.15 Close the receiver method through configuration-specific regression (p. 9287)

Why the selected alternative fits: Both derived versions with processing identities and an explanation of the difference.

Distinguishing consideration: compare this with option A, “A modified native file made to match the new conclusion”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Close the receiver method through configuration-specific regression.

V011-C16-MCQ-093. What should final release do with unresolved sample discontinuity or event-coverage limits?

A. Assume repeated use has established validity

B. Replace them with a generic confidence percentage

C. Keep them visible and narrow the accepted claim where needed

D. Hide them if the main plot is persuasive

Answer: C. A useful bounded method can remain valid in a narrower domain.

Source: §16.15 Close the receiver method through configuration-specific regression (p. 9287)

Why the selected alternative fits: Keep them visible and narrow the accepted claim where needed.

Distinguishing consideration: compare this with option A, “Assume repeated use has established validity”; that competing statement does not meet the question’s stated requirement.

V011-C16-MCQ-094. Why is a common clock a possible dependency across two receiver channels?

A. It can contribute a shared spur or timing error

B. It makes every RF line externally generated

C. It guarantees all channel errors are independent

D. It eliminates reference-path coupling

Answer: A. Multiple channels can retain one instrumental cause. Source: §16.13 Hypothetical Case Adjudication: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance (p. 9285)

Why the selected alternative fits: It can contribute a shared spur or timing error.

Distinguishing consideration: compare this with option B, “It makes every RF line externally generated”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Hypothetical Case Adjudication: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

V011-C16-MCQ-095. Why retain parent-source and combiner purity during a nonlinear-product challenge?

A. They can generate the same product attributed to the receiver

B. They cannot create intermodulation

C. Only the receiver can produce products at combination frequencies

D. Their effects vanish after gain correction

Answer: A. A valid stage attribution must exclude or bound upstream contamination. Source: §16.4.3 Interpret hypothetical receiver records (p. 9268)

Why the selected alternative fits: They can generate the same product attributed to the receiver.

Distinguishing consideration: compare this with option B, “They cannot create intermodulation”; that competing statement does not meet the question’s stated requirement.

Basis and limitation: Chapter 16 — Interpret hypothetical receiver records.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-FIB-009. Substituted receivers can retain a common cause through shared clocks, power, software or _____.

Answer: antennas. Different hardware labels do not guarantee independent error structure. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why this term is required: “antennas” completes the stated technical proposition.

Question context: Substituted receivers can retain a common cause through shared clocks, power, software or _____

Basis and qualification: Chapter 16 — Localize an artifact by changing the stage that could create it.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

Copyright 2026, James M. Atkinson

V011-C16-FIB-010. A suitable known reference helps interpret a second receiver's _____.

Answer: nondetection. The path must be capable of revealing the feature under comparison. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why this term is required: “nondetection” completes the stated technical proposition.

Question context: A suitable known reference helps interpret a second receiver's _____

Basis and qualification: Chapter 16 — Localize an artifact by changing the stage that could create it.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

Copyright 2026, James M. Atkinson

V011-C16-FIB-011. An input termination can change source impedance as well as remove the antenna _____.

Answer: path. Its effect is not uniquely an external-source test. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why this term is required: “path” completes the stated technical proposition.

Question context: An input termination can change source impedance as well as remove the antenna _____

Basis and qualification: Chapter 16 — Localize an artifact by changing the stage that could create it.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

Copyright 2026, James M. Atkinson

V011-C16-FIB-012. A plausible decoded identifier can be stale, repeated or a false _____.

Answer: lock. Decoding alone does not establish physical attribution. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Why this term is required: “lock” completes the stated technical proposition.

Question context: A plausible decoded identifier can be stale, repeated or a false _____

Basis and qualification: Chapter 16 — Localize an artifact by changing the stage that could create it.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

V011-C16-FIB-013. The effect of one control depending on another's setting is an _____.

Answer: interaction. Crossed combinations expose conditional effects. Source: §16.4 Receiver challenges with interacting controls (p. 9262)

Why this term is required: “interaction” completes the stated technical proposition.

Question context: The effect of one control depending on another's setting is an _____

Basis and qualification: Chapter 16 — Receiver challenges with interacting controls.

Review: Chapter 16 — Receiver challenges with interacting controls.

Copyright 2026, James M. Atkinson

V011-C16-FIB-014. Factors should be defined by physical changes rather than front-panel _____.

Answer: labels. One menu operation can alter several relevant properties. Source: §16.4 Receiver challenges with interacting controls (p. 9262)

Why this term is required: “labels” completes the stated technical proposition.

Question context: Factors should be defined by physical changes rather than front-panel _____

Basis and qualification: Chapter 16 — Receiver challenges with interacting controls.

Review: Chapter 16 — Receiver challenges with interacting controls.

Copyright 2026, James M. Atkinson

V011-C16-FIB-015. An external reference selection may change frequency calibration and common-mode _____.

Answer: coupling. Connections and timing behavior can change too. Source: §16.4 Receiver challenges with interacting controls (p. 9262)

Why this term is required: “coupling” completes the stated technical proposition.

Question context: An external reference selection may change frequency calibration and common-mode _____

Basis and qualification: Chapter 16 — Receiver challenges with interacting controls.

Review: Chapter 16 — Receiver challenges with interacting controls.

Copyright 2026, James M. Atkinson

V011-C16-FIB-016. Switch bypass can change insertion loss, impedance, signal route and control _____.

Answer: transients. It is not automatically a transparent single-property intervention. Source: §16.4 Receiver challenges with interacting controls (p. 9262)

Why this term is required: “transients” completes the stated technical proposition.

Question context: Switch bypass can change insertion loss, impedance, signal route and control _____

Basis and qualification: Chapter 16 — Receiver challenges with interacting controls.

Review: Chapter 16 — Receiver challenges with interacting controls.

Copyright 2026, James M. Atkinson

V011-C16-FIB-017. Two factors with two states each yield _____ combinations in a complete crossed design.

Answer: four. Every state of each factor is paired with both states of the other.

Source: §16.4.1 Arrange the comparisons before examining their outcomes (p. 9264)

Why this term is required: “four” completes the stated technical proposition.

Question context: Two factors with two states each yield _____ combinations in a complete crossed design

Basis and qualification: Chapter 16 — Arrange the comparisons before examining their outcomes.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

Copyright 2026, James M. Atkinson

V011-C16-FIB-018. Switch states should be compared within each reference _____ to expose conditional effects.

Answer: state. Pooling without labels can conceal interaction. Source: §16.4.1 Arrange the comparisons before examining their outcomes (p. 9264)

Why this term is required: “state” completes the stated technical proposition.

Question context: Switch states should be compared within each reference _____ to expose conditional effects

Basis and qualification: Chapter 16 — Arrange the comparisons before examining their outcomes.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

Copyright 2026, James M. Atkinson

V011-C16-FIB-019. Unavailable state combinations must be recorded as _____ comparisons.

Answer: missing. The remaining observations cannot silently supply them. Source: §16.4.1 Arrange the comparisons before examining their outcomes (p. 9264)

Why this term is required: “missing” completes the stated technical proposition.

Question context: Unavailable state combinations must be recorded as _____ comparisons

Basis and qualification: Chapter 16 — Arrange the comparisons before examining their outcomes.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

Copyright 2026, James M. Atkinson

V011-C16-FIB-020. The response should be defined at a physical reference _____ before acquisition.

Answer: plane. Corrections and uncertainty then refer to a consistent quantity.

Source: §16.4.1 Arrange the comparisons before examining their outcomes (p. 9264)

Why this term is required: “plane” completes the stated technical proposition.

Question context: The response should be defined at a physical reference _____ before acquisition

Basis and qualification: Chapter 16 — Arrange the comparisons before examining their outcomes.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

Copyright 2026, James M. Atkinson

V011-C16-FIB-021. Binary visibility can conceal an ordinary change in _____.

Answer: sensitivity. A feature may cross threshold while its physical source persists.

Source: §16.4.1 Arrange the comparisons before examining their outcomes (p. 9264)

Why this term is required: “sensitivity” completes the stated technical proposition.

Question context: Binary visibility can conceal an ordinary change in _____

Basis and qualification: Chapter 16 — Arrange the comparisons before examining their outcomes.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

Copyright 2026, James M. Atkinson

V011-C16-FIB-022. Linear power, logarithmic level and threshold crossing are different response _____.

Answer: definitions. Their differences do not answer identical questions. Source: §16.4.1 Arrange the comparisons before examining their outcomes (p. 9264)

Why this term is required: “definitions” completes the stated technical proposition.

Question context: Linear power, logarithmic level and threshold crossing are different response _____

Basis and qualification: Chapter 16 — Arrange the comparisons before examining their outcomes.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

Copyright 2026, James M. Atkinson

V011-C16-FIB-023. An observed interaction narrows the problem but does not locate the responsible _____.

Answer: circuit. Several physical dependencies may explain the same pattern.

Source: §16.4.1 Arrange the comparisons before examining their outcomes (p. 9264)

Why this term is required: “circuit” completes the stated technical proposition.

Question context: An observed interaction narrows the problem but does not locate the responsible _____

Basis and qualification: Chapter 16 — Arrange the comparisons before examining their outcomes.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

Copyright 2026, James M. Atkinson

V011-C16-FIB-024. A third uncontrolled condition that tracks factor settings can create _____.

Answer: confounding. State association alone need not isolate the proposed mechanism. Source: §16.4.1 Arrange the comparisons before examining their outcomes (p. 9264)

Why this term is required: “confounding” completes the stated technical proposition.

Question context: A third uncontrolled condition that tracks factor settings can create _____

Basis and qualification: Chapter 16 — Arrange the comparisons before examining their outcomes.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

V011-C16-FIB-025. A check reference should exercise the actual _____ being compared.

Answer: function. A CW tone does not test every burst or wideband capability.

Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why this term is required: “function” completes the stated technical proposition.

Question context: A check reference should exercise the actual _____ being compared

Basis and qualification: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

Copyright 2026, James M. Atkinson

V011-C16-FIB-026. A comfortable strong reference does not establish behavior near the observation _____.

Answer: limit. Weak-signal capability needs an appropriate test. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why this term is required: “limit” completes the stated technical proposition.

Question context: A comfortable strong reference does not establish behavior near the observation _____

Basis and qualification: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

Copyright 2026, James M. Atkinson

V011-C16-FIB-027. Comparisons must preserve the same reference plane or correct added _____.

Answer: paths. A bypass cable or new filter is not automatically transparent. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why this term is required: “paths” completes the stated technical proposition.

Question context: Comparisons must preserve the same reference plane or correct added _____

Basis and qualification: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

Copyright 2026, James M. Atkinson

V011-C16-FIB-028. Shared correction uncertainties should be retained through their _____.

Answer: covariance. Separate states can share calibration influences. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why this term is required: “covariance” completes the stated technical proposition.

Question context: Shared correction uncertainties should be retained through their _____

Basis and qualification: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

Copyright 2026, James M. Atkinson

V011-C16-FIB-029. A state lacking characterization may support an observation but not the same _____ comparison.

Answer: quantitative. The numerical correction and uncertainty scope are incomplete. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why this term is required: “quantitative” completes the stated technical proposition.

Question context: A state lacking characterization may support an observation but not the same _____ comparison

Basis and qualification: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

Copyright 2026, James M. Atkinson

V011-C16-FIB-030. Transition records should be separated from _____-state records.

Answer: settled. Relocking, switching impulses and recovery can create different behavior. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why this term is required: “settled” completes the stated technical proposition.

Question context: Transition records should be separated from _____-state records

Basis and qualification: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

Copyright 2026, James M. Atkinson

V011-C16-FIB-031. Removing a transition from one estimator must not erase it from the evidence _____.

Answer: record. The exclusion needs a reason and retained source. Source: §16.4.2 Preserve comparable observation capability (p. 9266)

Why this term is required: “record” completes the stated technical proposition.

Question context: Removing a transition from one estimator must not erase it from the evidence _____

Basis and qualification: Chapter 16 — Preserve comparable observation capability.

Review: Chapter 16 — Preserve comparable observation capability.

V011-C16-FIB-062. The likelihood ratio is p(D given H1) divided by _____.

Answer: p(D given H0). Both hypotheses and their data models must be defined.

Source: §16.11 Quantitative Model for Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance (p. 9282)

Why this term is required: "p(D given H0)" completes the stated technical proposition.

Question context: The likelihood ratio is p(D given H1) divided by _____

Basis and qualification: Chapter 16 — Quantitative Model for Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

Review: Chapter 16 — Quantitative Model for Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

V011-C16-FIB-065. A count of favorable tests does not supply numerical _____.

Answer: likelihoods. Dependence and model validity cannot be replaced by a tally.

Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

Why this term is required: “likelihoods” completes the stated technical proposition.

Question context: A count of favorable tests does not supply numerical _____

Basis and qualification: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

Copyright 2026, James M. Atkinson

V011-C16-FIB-066. A spectrum and EVM report from the same samples have a shared data _____.

Answer: source. Different output labels do not establish independence. Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

Why this term is required: “source” completes the stated technical proposition.

Question context: A spectrum and EVM report from the same samples have a shared data _____

Basis and qualification: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

Copyright 2026, James M. Atkinson

V011-C16-FIB-067. Two tools using the same decoder share a processing _____.

Answer: dependency. Their agreement can repeat the same implementation error.

Source: §16.5 Integration with Direction, Wireline, Optical, and Physical Evidence (p. 9274)

Why this term is required: “dependency” completes the stated technical proposition.

Question context: Two tools using the same decoder share a processing _____

Basis and qualification: Chapter 16 — Integration with Direction, Wireline, Optical, and Physical Evidence.

Review: Chapter 16 — Integration with Direction, Wireline, Optical, and Physical Evidence.

Essay Questions

[Essay instructions: Each essay must contain 3,500–5,000 words in total. Address the ten subject prompts below in the order presented, developing approximately 350–500 words for each prompt. Begin with an introduction establishing the question, scope and thesis. Conclude with a synthesis that draws together all ten prompts into one coherent closing argument. Count the introduction and conclusion within the overall word limit.]

V011-C16-ESSAY-001. Design an architecture-based challenge sequence for an unexplained spectral component.

- Opening: Present a thesis that answers this precise question: Design an architecture-based challenge sequence for an unexplained spectral component. Identify which evidence would falsify the proposed conclusion Source: §16.21 Nonlinear fingerprinting without circular source attribution (p. 9303)
- Core terminology and scope: Define Design, challenge, sequence in the question's particular technical setting; explain how unexplained, spectral, component differ if that distinction would change the analysis of "Design an architecture-based challenge sequence for an unexplained spectral component" Source: §16.21 Nonlinear fingerprinting without circular source attribution (p. 9303)
- Problem statement and purpose: Frame the actual measurement or decision in the question. Map plausible sources before and after controls, specify at least two competing predictions, preserve desired references, and include unsuccessful tests Source: §16.21 Nonlinear fingerprinting without circular source attribution (p. 9303)
- Physical and computational context: Reconstruct the physical, mathematical or software mechanism connecting an architecture-based challenge sequence for an unexplained spectral component to the claimed result, following "Localize an artifact by changing the stage that could create it"; name the intermediate states and measurable outputs Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Copyright 2026, James M. Atkinson

- Assumptions, conditions and reference planes: State the testable assumptions, configuration states and reference planes for an architecture-based challenge sequence for an unexplained spectral component. Distinguish conditional movement or scaling from unique source attribution Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)
- Analytical framework: Identify the equation, calibration or evidential decision test in “Challenge-Test Design” that resolves the question about an architecture-based challenge sequence for an unexplained spectral component; derive the relevant result with units and stated validity conditions Source: §16.2 Challenge-Test Design (p. 9258)
- Evidence and method: Specify the native observations, control records and calculations that would resolve an architecture-based challenge sequence for an unexplained spectral component. Distinguish conditional movement or scaling from unique source attribution Source: §16.21 Nonlinear fingerprinting without circular source attribution (p. 9303)
- Worked application or illustrative case: Build a worked example of “an architecture-based challenge sequence for an unexplained spectral component”, addressing this associated condition: Map plausible sources before and after controls, specify at least two competing predictions, preserve desired.... Map plausible sources before and after controls, specify at least two competing predictions, preserve desired references, and include unsuccessful tests Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Copyright 2026, James M. Atkinson

- Alternative explanations and failure modes: Construct two plausible technical explanations for “an architecture-based challenge sequence for an unexplained spectral component”. Using “Challenge-Test Design”, specify a discriminator and the result expected under each explanation Source: §16.2 Challenge-Test Design (p. 9258)
- Uncertainty and evidential limits: Quantify or bound the uncertainties that matter to an architecture-based challenge sequence for an unexplained spectral component, including the effect of missing measurements and inconsistent operating conditions Source: §16.23 Probabilistic evidence must preserve conditional assumptions (p. 9307)
- Scholarly synthesis and implications: Explain what the result about an architecture-based challenge sequence for an unexplained spectral component authorises the investigator or engineer to claim, and what stronger proposition remains unsupported Source: §16.21 Nonlinear fingerprinting without circular source attribution (p. 9303)
- Closing: Conclude by answering “Design an architecture-based challenge sequence for an unexplained spectral component” using only the demonstrated evidence; state the remaining decisive verification step Source: §16.21 Nonlinear fingerprinting without circular source attribution (p. 9303)

V011-C16-ESSAY-002. Analyze corrected attenuation scaling as evidence and as a limitation.

- Opening: Present a thesis that answers this precise question: Analyze corrected attenuation scaling as evidence and as a limitation. Identify which evidence would falsify the proposed conclusion Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)
- Core terminology and scope: Define corrected, attenuation, scaling in the question's particular technical setting; explain how limitation, measurement, evidence differ if that distinction would change the analysis of "Analyze corrected attenuation scaling as evidence and as a limitation" Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)
- Problem statement and purpose: Frame the actual measurement or decision in the question. Reconstruct −83.2 dBm and signed −0.2 dB from the chapter example, compare with 0.7 dB uncertainty, and explain compatible external-like pathways including receiver leakage entering through the... Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)
- Physical and computational context: Reconstruct the physical, mathematical or software mechanism connecting corrected attenuation scaling as evidence and as a limitation to the claimed result, following "Findings, Reports, and Decision Ladders"; name the intermediate states and measurable outputs Source: §16.6 Findings, Reports, and Decision Ladders (p. 9275)

Copyright 2026, James M. Atkinson

- Assumptions, conditions and reference planes: State the testable assumptions, configuration states and reference planes for corrected attenuation scaling as evidence and as a limitation. Require additional linkage for attribution Source: §16.6 Findings, Reports, and Decision Ladders (p. 9275)
- Analytical framework: Identify the equation, calibration or evidential decision test in “Nonlinear fingerprinting without circular source attribution” that resolves the question about corrected attenuation scaling as evidence and as a limitation; derive the relevant result with units and stated validity conditions Source: §16.21 Nonlinear fingerprinting without circular source attribution (p. 9303)
- Evidence and method: Specify the native observations, control records and calculations that would resolve corrected attenuation scaling as evidence and as a limitation. Require additional linkage for attribution Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)
- Worked application or illustrative case: Build a worked example of “corrected attenuation scaling as evidence and as a limitation”, addressing this associated condition: Reconstruct −83.2 dBm and signed −0.2 dB from the chapter example, compare with 0.7 dB uncertainty, and.... Discussion Questions

[Discussion instructions: For each discussion question, prepare approximately 500 spoken words for delivery over 2.5–3 minutes (approximately 167–200 words per minute). Address the ten subject prompts below in their stated order. Use the opening to frame the issue and the closing to synthesise the principal findings, conclusions and unresolved questions.]

Copyright 2026, James M. Atkinson

V011-C16-DISCUSSION-001. A line follows external-like attenuation scaling. What should be claimed and what tested next?

- 01. Moderator, opening proposition: Introduce the exact dispute, “A line follows external-like attenuation scaling. What should be claimed and what tested next?” Put this particular dispute to the panel: A line follows external-like attenuation scaling. What should be claimed and what tested next. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

- 02. Student A, terminology and scope: Agree the operational meanings of line, follows, attenuation and scaling, claimed, tested in “A line follows external-like attenuation scaling. What should be claimed and what tested next”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of A line follows external-like attenuation scaling; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §16.16 Falsification-led survey closure and the evidential status of negative observations (p. 9288)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Falsification-led survey closure and the evidential status of negative observations”. Do not infer authorization or unique external origin Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §16.16 Falsification-led survey closure and the evidential status of negative observations (p. 9288)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A line follows external-like attenuation scaling; explain what each record can establish State

Copyright 2026, James M. Atkinson

what the existing record establishes, what it does not establish, and which further measurement would change your opinion. Source: §16.20 An intervention matrix that separates mechanism, state and common error (p. 9301)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “Falsification-led survey closure and the evidential status of negative observations”. Do not infer authorization or unique external origin Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §16.16 Falsification-led survey closure and the evidential status of negative observations (p. 9288)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. Claim compatibility at the stated plane and uncertainty, retain possible receiver emission through the input path, and select a source/path-discriminating intervention Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate between them without changing the measurand. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Copyright 2026, James M. Atkinson

- 08. Student D, answer to Student E: Design a discriminating experiment involving A line follows external-like attenuation scaling: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A line follows external-like attenuation scaling; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §16.20 An intervention matrix that separates mechanism, state and common error (p. 9301)

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving A line follows external-like attenuation scaling: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Present a repeatable, authorised test with the receiver settings,

Copyright 2026, James M. Atkinson

controlled variable, expected responses and a rejection criterion. Ask Student H to identify an alternative that could survive the proposed test. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

- 11. Student H, adversarial challenge and confounding alternatives: For the precise observation involving A line follows external-like attenuation scaling, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Question Student G about a specific artifact or uncontrolled variable. Demand a control experiment that would expose a false positive or incorrect source attribution. Source: §16.16 Falsification-led survey closure and the evidential status of negative observations (p. 9288)

- 12. Student G, revised experimental answer: Address Student H's confounding mechanism by revising the controlled test described in the preceding prompt. Design a discriminating experiment involving A line follows external-like attenuation scaling: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Say precisely what observation would lead the panel to retain, qualify or reject the conclusion. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Copyright 2026, James M. Atkinson

- 13. Student I, uncertainty and inferential limits: Assess uncertainty and evidential scope for A line follows external-like attenuation scaling. Do not infer authorization or unique external origin Explain the relevant statistical or calibration uncertainty, the range of defensible claims, and why the question cannot be settled by visual appearance or a single unqualified reading. Source: §16.20 An intervention matrix that separates mechanism, state and common error (p. 9301)

- 14. Student J, Socratic challenge to Student I: For the precise observation involving A line follows external-like attenuation scaling, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Ask Student I whether the proposed uncertainty statement accounts for the actual receiver state, sample coverage and possible instrumental artifacts. Request an explicit statement of what evidence would reverse the conclusion. Source: §16.16 Falsification-led survey closure and the evidential status of negative observations (p. 9288)

- 15. Student I, quantified and qualified reply: Assess uncertainty and evidential scope for A line follows external-like attenuation scaling. Do not infer authorization or unique external origin Respond point by point to Student J. Distinguish a verified observation from a conditional inference and name the missing datum, sensitivity test

Copyright 2026, James M. Atkinson

or uncertainty term that limits confidence. Source: §16.20 An intervention matrix that separates mechanism, state and common error (p. 9301)

- 16. Student K, authority and evidential discipline: Determine which authority, calibration and reporting safeguards apply to the particular claim about A line follows external-like attenuation scaling and What should be claimed and what tested next; exclude protections irrelevant to the scenario Question Student F about the custody and reproducibility of the proposed records and ask Student G whether the discriminatory test remains within authorised laboratory and field boundaries. Source: §16.17 An evidence-closure matrix that links physical tests to permissible forensic propositions (p. 9291)

- 17. Peer panel, negotiated consensus and residual dissent: Draft a narrow consensus about “A line follows external-like attenuation scaling”, addressing “What should be claimed and what tested next”; specify the exact measurement or evidential gap on which the speakers still differ Require Students A, B, D, G and I to respond to at least one objection raised by another speaker before voting. Record both the narrow agreement and the specific contested proposition that remains unresolved. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

Copyright 2026, James M. Atkinson

- 18. Moderator, reasoned disposition and follow-up: Record a final recommendation on “A line follows external-like attenuation scaling. What should be claimed and what tested next”, specifying the next test, responsible measurement record and limit of the conclusion Summarise the strongest evidence for and against the resolution of “A line follows external-like attenuation scaling. What should be claimed and what tested next”. Allocate the next measurement and documentary action to named student roles, and require each participant to distinguish accepted evidence from an unsupported assertion. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

V011-C16-DISCUSSION-002. Two receivers show the same line while sharing clock and antenna. Is that independent confirmation?

- 01. Moderator, opening proposition: Introduce the exact dispute, “Two receivers show the same line while sharing clock and antenna. Is that independent confirmation?” Put this particular dispute to the panel: Two receivers show the same line while sharing clock and antenna. Is that independent confirmation. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

- 02. Student A, terminology and scope: Agree the operational meanings of receivers, line, sharing and clock, antenna, confirmation in “Two receivers show the same line while sharing clock and antenna. Is that independent confirmation”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of Two receivers show the same line while sharing clock and antenna; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Localize an artifact by changing the stage that could create it”. Agreement is useful but may repeat the same instrument or coupling cause Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of Two receivers show the same line while sharing clock and antenna; explain what each record can

establish State what the existing record establishes, what it does not establish, and which further measurement would change your opinion. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “Localize an artifact by changing the stage that could create it”. Agreement is useful but may repeat the same instrument or coupling cause Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. Map shared causes and carry suitable references; change a relevant dependency where feasible Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate between them without changing the measurand. Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

Copyright 2026, James M. Atkinson

- 08. Student D, answer to Student E: Design a discriminating experiment involving Two receivers show the same line while sharing clock and antenna: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §16.7 Reconcile evidence without assigning unsupported probabilities (p. 9276)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of Two receivers show the same line while sharing clock and antenna; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving Two receivers show the same line while sharing clock and antenna: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Present a repeatable, authorised test with the

V011-C16-DISCUSSION-017. A report calls a waveform a confirmed surveillance function based on frequency and modulation. What evidence is missing?

- 01. Moderator, opening proposition: Introduce the exact dispute, “A report calls a waveform a confirmed surveillance function based on frequency and modulation. What evidence is missing?” Put this particular dispute to the panel: A report calls a waveform a confirmed surveillance function based on frequency and modulation. What evidence is missing. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §16.6 Findings, Reports, and Decision Ladders (p. 9275)

- 02. Student A, terminology and scope: Agree the operational meanings of calls, confirmed, surveillance and function, based, missing in “A report calls a waveform a confirmed surveillance function based on frequency and modulation. What evidence is missing”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §16.6 Findings, Reports, and Decision Ladders (p. 9275)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of A report calls a waveform a confirmed surveillance function based on frequency and modulation; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §16.5 Integration with Direction, Wireline, Optical, and Physical Evidence (p. 9274)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Integration with Direction, Wireline, Optical, and Physical Evidence”. Use a narrower finding category until those links are demonstrated Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §16.5 Integration with Direction, Wireline, Optical, and Physical Evidence (p. 9274)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of A report calls a waveform a

each record can establish State what the existing record establishes, what it does not establish, and which further measurement would change your opinion. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

- 06. Student D, competing mechanism: Debate the governing receiver or signal mechanism in “Program Governance and Peer Review”. A reusable artifact record should guide testing without turning one incident into universal doctrine Explain a materially different receiver or signal mechanism, state its predicted signature, and invite Student E to challenge whether it fits the same observed trace or native sample record. Source: §16.10 Program Governance and Peer Review (p. 9281)

- 07. Student E, cross-examination of the competing mechanism: Identify the competing options in the question. Recover the tested configurations, stimulus and mechanism, require applicability checks and preserve alternatives Put two specific questions to Student D about the stated competing options and the instrument configuration. Ask which setting or observation would discriminate between them without changing the measurand. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

Copyright 2026, James M. Atkinson

- 08. Student D, answer to Student E: Design a discriminating experiment involving One established artifact becomes a blanket exclusion rule for all future surveys: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Respond to both cross-examination questions, specify the independent control condition and expected result, and identify how you would document an unexpected observation. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

- 09. Student F, original evidence and provenance: Specify the original trace, I/Q record, calibration state or field note actually needed to test the alternative interpretations of One established artifact becomes a blanket exclusion rule for all future surveys; explain what each record can establish Describe the native record, metadata and calibration evidence that the panel must actually examine. Ask Student G which datum should be collected first and what uncertainty remains if it is missing. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

- 10. Student G, discriminatory measurement design: Design a discriminating experiment involving One established artifact becomes a blanket exclusion rule for all future surveys: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Present a repeatable, authorised test

Copyright 2026, James M. Atkinson

with the receiver settings, controlled variable, expected responses and a rejection criterion. Ask Student H to identify an alternative that could survive the proposed test. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

- 11. Student H, adversarial challenge and confounding alternatives: For the precise observation involving One established artifact becomes a blanket exclusion rule for all future surveys, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Question Student G about a specific artifact or uncontrolled variable. Demand a control experiment that would expose a false positive or incorrect source attribution. Source: §16.10 Program Governance and Peer Review (p. 9281)

- 12. Student G, revised experimental answer: Address Student H's confounding mechanism by revising the controlled test described in the preceding prompt. Design a discriminating experiment involving One established artifact becomes a blanket exclusion rule for all future surveys: specify the altered receiver state or source condition, predicted change, test statistic and rejection criterion Say precisely what observation would lead the panel to retain, qualify or reject the conclusion. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

Copyright 2026, James M. Atkinson

- 13. Student I, uncertainty and inferential limits: Assess uncertainty and evidential scope for One established artifact becomes a blanket exclusion rule for all future surveys. A reusable artifact record should guide testing without turning one incident into universal doctrine Explain the relevant statistical or calibration uncertainty, the range of defensible claims, and why the question cannot be settled by visual appearance or a single unqualified reading. Source: §16.3 Localize an artifact by changing the stage that could create it (p. 9260)

- 14. Student J, Socratic challenge to Student I: For the precise observation involving One established artifact becomes a blanket exclusion rule for all future surveys, formulate an instrumental artifact or confounding alternative, then identify the control measurement that would expose it Ask Student I whether the proposed uncertainty statement accounts for the actual receiver state, sample coverage and possible instrumental artifacts. Request an explicit statement of what evidence would reverse the conclusion. Source: §16.10 Program Governance and Peer Review (p. 9281)

- 15. Student I, quantified and qualified reply: Assess uncertainty and evidential scope for One established artifact becomes a blanket exclusion rule for all future surveys. A reusable artifact record should guide testing without turning one incident into universal

V011-C16-DISCUSSION-025. The method is valid for conducted steady signals but not yet for short bursts after retune. How should release be bounded?

- 01. Moderator, opening proposition: Introduce the exact dispute, “The method is valid for conducted steady signals but not yet for short bursts after retune. How should release be bounded?” Put this particular dispute to the panel: The method is valid for conducted steady signals but not yet for short bursts after retune. How should release be bounded. Ask speakers to identify the result or operational decision at stake Invite two students to propose competing answers, and ask each to name a measurable consequence that could disprove the position. Source: §16.15 Close the receiver method through configuration-specific regression (p. 9287)

- 02. Student A, terminology and scope: Agree the operational meanings of method, conducted, steady and bursts, retune, release in “The method is valid for conducted steady signals but not yet for short bursts after retune. How should release be bounded”; state which definitions materially change the competing positions Ask Student B which definition would most materially change the outcome and request a specific example from the stated receiver scenario. Source: §16.15 Close the receiver method through configuration-specific regression (p. 9287)

Copyright 2026, James M. Atkinson

- 03. Student B, affirmative technical position: Ask one participant to defend and another to challenge the proposed treatment of The method is valid for conducted steady signals but not yet for short bursts after retune; require both to name a decisive instrument observation Give a defensible initial conclusion, identify the instrument state on which it depends, and pass a direct question to Student C about a plausible weakness. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

- 04. Student C, first Socratic examination of Student B: Debate the governing receiver or signal mechanism in “Write findings that preserve the strength and limit of each test”. Useful narrower results need not be overstated as universal capability Ask Student B two focused questions: Which physical or digital stage could produce the observed result, and what independent observation could contradict that explanation? Do not accept a repeat of the opening claim as an answer. Source: §16.8 Write findings that preserve the strength and limit of each test (p. 9278)

- 05. Student B, evidence-based answer to Student C: Respond directly to the mechanism and falsification questions. Specify the original trace, I/Q record, calibration state or field note actually needed to

Chapter 16 Answer Keys and Guidance

The essay and discussion guidance below identifies expected mechanisms, methods and evidence. A defensible alternative conclusion must state its assumptions, reasoning and limitations.

Copyright 2026, James M. Atkinson

Essay Guidance

V011-C16-ESSAY-001 — Map plausible sources before and after controls, specify at least two competing predictions, preserve desired references, and include unsuccessful tests. Distinguish conditional movement or scaling from unique source attribution.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

V011-C16-ESSAY-002 — Reconstruct −83.2 dBm and signed −0.2 dB from the chapter example, compare with 0.7 dB uncertainty, and explain compatible external-like pathways including receiver leakage entering through the input. Require additional linkage for attribution.

Review: Chapter 16 — Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

V011-C16-ESSAY-003 — Map shared antennas, clocks, power, software and corrections; carry a suitable reference through both paths; compare noise, bandwidth and timing. State what agreement or disappearance can support under the demonstrated scope.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

V011-C16-ESSAY-004 — Describe physical changes in each factor, all four meaningful combinations, fixed response plane and criterion, known-reference checks, actual order and missing states. Explain conditional effects without assigning unsupported component causation.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

Copyright 2026, James M. Atkinson

V011-C16-ESSAY-005 — Show how the effect of one factor can depend on another, discuss joint coupling, sensitivity/blocker behavior and third-condition confounding, and propose independent follow-ups that distinguish these alternatives.

Review: Chapter 16 — Receiver challenges with interacting controls.

V011-C16-ESSAY-006 — Match references to frequency mapping, relevant level, bandwidth, timing, trigger and record continuity. Explain why a strong CW check cannot support every negative observation and retain state-specific corrections and limits.

Review: Chapter 16 — Preserve comparable observation capability.

V011-C16-ESSAY-007 — Record relocking, switch impulses and recovery history, use validated usable intervals, and retain excluded transition records. If the feature occurs only during a transition, define a dedicated criterion rather than erase it.

Review: Chapter 16 — Preserve comparable observation capability.

V011-C16-ESSAY-008 — State the joint association under preserved capability, retain measured levels and observation limits, revisit original states, and propose reference/return-path tests. Explain why neither independent causation by both components nor universal absence follows.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-ESSAY-009 — Connect admitted parents and gain to a plausible loading mechanism, check actual parent levels and source/combiner purity, and control mismatch and gain trajectory. Use four-state evidence to narrow hypotheses without uniquely assigning a stage.

Review: Chapter 16 — Interpret hypothetical receiver records.

Copyright 2026, James M. Atkinson

V011-C16-ESSAY-010 — Retain permissive/strict outputs on field, valid-reference and independent noise-only records. Explain fitted versus held-out data and why rule changes cannot retrospectively establish the origin of every field event.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-ESSAY-011 — Define fresh intervention acquisitions, order control against drift, and grouping under nuisance conditions. Explain restricted order, retained group membership and why replotting or overlapping windows are not physical replication.

Review: Chapter 16 — Record repetition and the limits of the design.

V011-C16-ESSAY-012 — Show why within-session repetition cannot separate the effects, identify meaningful missing combinations, and propose a feasible crossed/blocking plan. If unavailable, state the unresolved comparison without imputing results.

Review: Chapter 16 — Record repetition and the limits of the design.

V011-C16-ESSAY-013 — Define each direct observable, reconcile time and state, identify common clocks/power/software and seek changes in error structure. Discuss multipath and phase centers where localization is used and avoid treating sensor count as independence.

Review: Chapter 16 — Integration with Direction, Wireline, Optical, and Physical Evidence.

V011-C16-ESSAY-014 — Distinguish classification, temporal correlation, localization, device linkage and authorization. Specify physical/operational linkage, information path, reproducibility and evidence continuity needed for the strongest claim and retain intermediate categories.

Review: Chapter 16 — Findings, Reports, and Decision Ladders.

Copyright 2026, James M. Atkinson

V011-C16-ESSAY-015 — Define corrected same-plane differences and their covariance-aware uncertainty, then state the separate requirements for a likelihood ratio, including hypotheses, positive denominator, dependence and selection. Explain why a discrepancy or favorable-test count is not attribution odds.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-ESSAY-016 — Use terminated input, known reference and noise-only processing with their distinct scopes. Bracket the actual observation, retain failures and checks after changes, and explain what none of the controls establishes universally.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-ESSAY-017 — Organize question, accepted native records, configuration, calculation, challenges and inference. Retain units, planes, normalization and uncertainty, name competing explanations, and prioritize the next discriminating test with omission limits.

Review: Chapter 16 — Write findings that preserve the strength and limit of each test.

V011-C16-ESSAY-018 — Identify exhibiting states, known stimulus or transition, predicted and observed response, successful challenge and mitigation. Include reproduction instructions and applicability limits so a later examiner can test whether the mechanism recurs.

Review: Chapter 16 — Write findings that preserve the strength and limit of each test.

Copyright 2026, James M. Atkinson

V011-C16-ESSAY-019 — Cover relevant amplitude/noise, conversion, dynamic range, images/spurs, timing, sample continuity, trigger, metadata and external path. Use stable references after consequential changes and retain calibration, repairs, software and correction history.

Review: Chapter 16 — Acceptance, Maintenance, and Lifecycle Control.

V011-C16-ESSAY-020 — Provide native data, configurations, calculations, calibration, challenges and alternatives; ask reviewers to reconstruct claims and limits. Resolve disagreement through further tests or explicit limitations, preserving errors and reversals rather than enforcing narrative consensus.

Review: Chapter 16 — Program Governance and Peer Review.

V011-C16-ESSAY-021 — Separate RF and optical direct observations, identify the joint intervention and shared dependencies, then propose separate crossed factors, reversals and a suitable known-reference test. State the provisional artifact hypothesis and remaining attribution limits.

Review: Chapter 16 — Hypothetical Case Adjudication: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

V011-C16-ESSAY-022 — Retain old and new states, select tests for actual deployed functions, rerun representative native records, preserve both derived versions and explain differences. Distinguish corrected interpretation from alteration of the original observation.

Review: Chapter 16 — Close the receiver method through configuration-specific regression.

Copyright 2026, James M. Atkinson

V011-C16-ESSAY-023 — Consider changed sensitivity, passband, impedance, trigger opportunity and coupling. Require mechanism-specific predictions and relevant capability references, preserve the original observation and state the strongest bounded inference.

Review: Chapter 16 — Challenge-Test and Evidence Release Gate.

V011-C16-ESSAY-024 — Use two receivers sharing a clock, spectrum/EVM from one record and two wrappers around one decoder. Explain the useful but dependent information, avoid unsupported multiplication, and propose an observation that changes the relevant error path.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-ESSAY-025 — Identify which functions remain accepted and which are limited by calibration, discontinuity, automatic state or coverage. Narrow the claim while retaining useful supported results, and define regression needed before extending the domain.

Review: Chapter 16 — Close the receiver method through configuration-specific regression.

Copyright 2026, James M. Atkinson

Discussion Guidance

V011-C16-DISCUSSION-001 — Claim compatibility at the stated plane and uncertainty, retain possible receiver emission through the input path, and select a source/path-discriminating intervention. Do not infer authorization or unique external origin.

Review: Chapter 16 — Hypothetical Applied Calculation: Receiver Artifacts, Challenge Tests, Survey Integration, Reporting, and Lifecycle Governance.

V011-C16-DISCUSSION-002 — Map shared causes and carry suitable references; change a relevant dependency where feasible. Agreement is useful but may repeat the same instrument or coupling cause.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

V011-C16-DISCUSSION-003 — Consider impedance change, removed external nonlinear elements and input-coupled instrument emissions, with capability checks. Preserve the narrow dependence rather than declare unique source identity.

Review: Chapter 16 — Localize an artifact by changing the stage that could create it.

V011-C16-DISCUSSION-004 — Cross the two settings where meaningful, characterize bundled physical changes, retain comparable references and revisit original states. The joint intervention alone cannot separate main and conditional effects.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

Copyright 2026, James M. Atkinson

V011-C16-DISCUSSION-005 — Report association with that joint state under tested limits, retain levels and reference evidence, and investigate shared paths or state-dependent sensitivity. Do not claim both components independently emit.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-DISCUSSION-006 — Mark the missing condition and resulting comparison limit, preserve the other observations and seek a physically meaningful alternative. Do not fill the cell by assumption.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

V011-C16-DISCUSSION-007 — Compare continuous corrected levels, noise and threshold behavior at a common plane, plus relevant weak references. Determine whether a sensitivity boundary creates the visible/not-visible pattern.

Review: Chapter 16 — Arrange the comparisons before examining their outcomes.

V011-C16-DISCUSSION-008 — Test burst duration, trigger path, dead time, settling and continuity with a suitable reference. The CW check supports only its own steady transfer capability.

Review: Chapter 16 — Preserve comparable observation capability.

V011-C16-DISCUSSION-009 — No; retain transition records, state timing and exclusion reasons, and define a dedicated transient comparison. Exclusion from one estimator is not evidence that the event is irrelevant.

Review: Chapter 16 — Preserve comparable observation capability.

Copyright 2026, James M. Atkinson

V011-C16-DISCUSSION-010 — Measure admitted parent levels, desired reference and source purity; compare gain states and evaluate mismatch or AGC changes. The filter's multiple physical effects leave alternatives.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-DISCUSSION-011 — Use independently retained valid and noise-only records under both rules, disclose fitted choices and preserve outputs. Do not infer field-event origin from training success.

Review: Chapter 16 — Interpret hypothetical receiver records.

V011-C16-DISCUSSION-012 — Distinguish presentation/analysis repetitions from fresh acquisitions revisiting the physical state. Use actual independent or modeled repetitions to assess variability and retain the original source identity.

Review: Chapter 16 — Record repetition and the limits of the design.

V011-C16-DISCUSSION-013 — Clock setting and temporal/environmental change are associated. Use interleaved or blocked comparisons where possible, retain order and temperature, and state limits if the missing contrast cannot be obtained.

Review: Chapter 16 — Record repetition and the limits of the design.

V011-C16-DISCUSSION-014 — Not necessarily; document the restriction, identify possible confounding, preserve within-block comparisons and narrow conclusions. Do not claim randomization that did not occur.

Review: Chapter 16 — Record repetition and the limits of the design.

V011-C16-DISCUSSION-015 — No; the missing crossed session/state comparison remains. Obtain meaningful additional combinations or report the confound rather than assigning the difference to the clock.

Review: Chapter 16 — Record repetition and the limits of the design.

Copyright 2026, James M. Atkinson

V011-C16-DISCUSSION-016 — Their direct observables, clock/state alignment, shared dependencies and possible common control. Optical activity alone does not establish an RF information path.

Review: Chapter 16 — Integration with Direction, Wireline, Optical, and Physical Evidence.

V011-C16-DISCUSSION-017 — Physical or operational linkage, information path, authorization status, reproducibility and continuity. Use a narrower finding category until those links are demonstrated.

Review: Chapter 16 — Findings, Reports, and Decision Ladders.

V011-C16-DISCUSSION-018 — Only as a hypothesis until stage/state controls discriminate alternatives. Preserve the discrepancy, examine gain control, products and calibration scope, and avoid cause identification from magnitude alone.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-DISCUSSION-019 — Defined hypotheses and defensible likelihood models including dependence and selection. Without them, report discriminating consequences and unresolved alternatives directly.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-DISCUSSION-020 — Identify their shared native samples and processing dependencies, explain complementary measurements, and avoid counting them as independent observations solely from output labels.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

Copyright 2026, James M. Atkinson

V011-C16-DISCUSSION-021 — Identify the affected function and last valid state, preserve data and checks, then narrow, repeat or qualify dependent conclusions according to evidence. Do not discard the failure or apply unsupported blanket correction.

Review: Chapter 16 — Reconcile evidence without assigning unsupported probabilities.

V011-C16-DISCUSSION-022 — Provide native evidence and model assumptions, identify the discriminating disagreement, obtain further tests where authorized or disclose the limit. Editorial agreement cannot substitute for evidence.

Review: Chapter 16 — Program Governance and Peer Review.

V011-C16-DISCUSSION-023 — Old/new configurations, accepted references, exact processing and representative native inputs; compare both derived outputs and explain changed alignment or correction. A startup test does not cover every measurement function.

Review: Chapter 16 — Close the receiver method through configuration-specific regression.

V011-C16-DISCUSSION-024 — Recover the tested configurations, stimulus and mechanism, require applicability checks and preserve alternatives. A reusable artifact record should guide testing without turning one incident into universal doctrine.

Review: Chapter 16 — Write findings that preserve the strength and limit of each test.

Copyright 2026, James M. Atkinson

V011-C16-DISCUSSION-025 — State the accepted steady-signal domain and explicit timing/coverage limitation, retain needed references and define further validation. Useful narrower results need not be overstated as universal capability.

Review: Chapter 16 — Close the receiver method through configuration-specific regression.

Copyright 2026, James M. Atkinson

Chapter Glossary

ARCHITECTURE MAP: A representation placing plausible mechanisms and accessible controls at their locations in the measurement chain. It supports predictions about how a controlled change should affect a candidate cause. A front-panel setting is not a causal location by itself, especially when the setting changes several paths or states together.

ARTIFACT RECORD: A reusable account of a demonstrated measurement artifact, including its affected configurations, stimulus or transition, predicted and observed response, challenge evidence and accepted mitigation. Its scope remains the tested conditions. A single incident should not become a universal rule about other receivers or environments without additional evidence.

ARTIFACT TAXONOMY: An organized inventory of mechanisms that could produce an observed indication through the receiver, installed path or environment. Its purpose is to generate competing explanations and discriminating tests. Membership in a familiar category does not identify the cause of a particular observation without supporting architecture and challenge evidence.

BLINDING: A design measure that limits access to information capable of influencing a comparison or interpretation before the relevant observations or decisions are recorded. It can reduce confirmation bias when feasible. Its role and restrictions must be documented; merely calling a test blinded does not establish independent observations or comparable receiver states.

Copyright 2026, James M. Atkinson

CHALLENGE TEST: A controlled intervention selected because competing causal explanations predict different observable consequences. The comparison retains enough configuration, desired-signal transfer and observation capability to interpret the change; an unexplained disappearance alone does not identify a mechanism.

CONDITIONAL EFFECT: The observed consequence of changing one factor at a specified setting of the other relevant factors. It may differ at another setting, indicating an interaction in the response. The result narrows the tested relationship without automatically identifying a faulty component or the unique physical cause.

CONFIGURATION COMPARABILITY: Established compatibility of reference planes, corrections, observation limits, timing, and relevant instrument states sufficient to support a specified comparison.

CONFOUNDING: An inability of the available design to separate the consequences of factors that vary together. Reference state and session are confounded when each state is observed in only one distinct session. More observations within the same incomplete arrangement do not establish the missing distinction.

CONTROL INTERACTION: Dependence of the observed effect of changing one control on the setting of another, evaluated for a declared response and measurement context.

Copyright 2026, James M. Atkinson

CROSS-DOMAIN CORROBORATION: Agreement among observations from different physical or information domains after their timing, state and dependencies have been reconciled. It can support a mechanism or linkage, but the domains may still share a cause. An optical observation establishes optical activity within its scope and does not automatically establish an RF source.

CROSSED CONTROL STATES: An experimental arrangement in which every selected setting of one control is observed with every selected setting of another, subject to documented physical feasibility and comparability.

DEVICE LINKAGE: Evidence connecting an observation to a particular physical device or its operation. A frequency, modulation label or plausible decoded identifier alone may be insufficient. The report distinguishes such linkage from mere temporal association, localization, authorization status and confirmation of an information path or surveillance function.

EVIDENCE CONTINUITY: The documented connection from the acquired observations through their configurations, processing and supporting records to the reported inference. It allows later review of what was observed and what was derived. Preserving this connection is distinct from asserting that every sample was acquired continuously; both may be relevant to a particular claim.

EXPERIMENTAL BLOCKING: Grouping observations under a declared nuisance condition while retaining the relevant comparisons within groups where practicable. It makes the condition explicit rather than removing it. If each reference setting occurs only in a different session, repetition within those sessions cannot recover the missing crossed comparison.

Copyright 2026, James M. Atkinson

FACTOR LEVEL: A specified physical setting or condition of a factor used in an experimental comparison. Its implementation can change several electrical or processing properties at once. Document the actual connections, terminations, routes and states rather than treating a convenient menu label as a uniquely isolated mechanism.

FALSE POSITIVE: Result incorrectly satisfying a detection or classification rule in the absence of the claimed phenomenon.

FINDING CATEGORY: The explicitly stated evidential status assigned to a reportable observation, such as normal occupancy, artifact, installation defect or unexplained signal. Categories allow a conclusion to remain proportionate to the completed work. Moving to a stronger category requires its additional evidence rather than a more confident adjective.

FUNCTIONAL ATTRIBUTION: An inference establishing the relevant operation or information function of a linked system. In the chapter's finding ladder, confirmation requires physical or operational linkage, an information path, authorization context, reproducible behavior and evidence continuity. A dramatic trace or recognizable modulation does not independently establish that complete claim.

HELD-OUT VALIDATION: Evaluation on records not used to select the fitted model, processing rule or decision setting. It supports a claim about behavior beyond the examples used for that choice. Reprocessing the same selected field events under a stricter rule does not by itself provide this independent validation.

Copyright 2026, James M. Atkinson

INDEPENDENT EVIDENCE: Evidence whose relevant error mechanisms and dependencies have been examined and are sufficiently distinct for the intended inference. Different sensors or software names alone do not supply that distinction. A useful additional observation changes the particular coupling, timing or processing path that could explain the existing agreement.

KNOWN-REFERENCE CONTROL: An observation of an appropriately specified reference used to establish the comparison capability of a configuration. Its waveform, level, frequency and timing must exercise the relevant function. Detecting a comfortable continuous tone does not establish performance for a weak burst beside a blocker or prove general absence after substitution.

LIKELIHOOD RATIO: The ratio of the probability or probability density assigned to the same data by two specified hypotheses, with a positive denominator for a finite result. It requires defensible models of the data and selection procedure. This chapter uses the definition to state that requirement and assigns no numerical odds to its artifact or attribution categories.

LOCALIZATION: An inference about where a source or coupling region is situated from spatially informative observations. Receiver evidence may contribute through direction or gradients, subject to propagation, geometry and calibration. Localization is a different evidential step from classifying a waveform or linking it to a particular device and function.

Copyright 2026, James M. Atkinson

MECHANISM PREDICTION: A stated consequence expected from a proposed physical or processing explanation under a specified intervention. Writing competing predictions before changing the setup gives the challenge a discriminating purpose. An observed match supports only the consequences tested and does not exclude alternatives that predict the same behavior.

NEGATIVE CONTROL: A comparison selected to test a specific alternative explanation under defined conditions. Examples include a terminated input or a noise-only record, each with its own scope. A successful control does not cover every field state, and failures must remain in the record alongside passes.

NORMALIZED RESPONSE ERROR: The difference between observations after the stated gain, attenuation and other required corrections have referred them to a comparable quantity and plane. Its uncertainty and receiver states determine the meaning of agreement. A discrepancy can motivate investigation of compression, internal products or state changes without uniquely naming the cause.

OBSERVATION LIMIT: The demonstrated boundary of what a specified configuration and record could reveal under the declared criterion. Nondetection above a supported limit is different from proof of complete absence. A substitution that changes sensitivity must retain suitable reference evidence before its negative result can support the intended comparison.

Copyright 2026, James M. Atkinson

REGRESSION TEST: A repeatable comparison with previously accepted results after a repair or a change in equipment, firmware, software, calibration or accessories. Checks are selected for the functions used by the deployed measurement configuration and retain their known references, accepted ranges and relevant states; a startup self-test covers only its own exercised functions.

REPLICATION: Fresh execution of an intervention and acquisition under the declared conditions to examine variability and reproducibility. Replotting one capture or dividing it into overlapping windows does not replicate the physical intervention. The repeated records must retain state, order and source conditions so their relationship can be assessed.

RESIDUAL RESPONSE: Instrument-generated indication remaining with a terminated or otherwise controlled input.

RESPONSE DEFINITION: The quantity or criterion fixed before evaluating experimental configurations, including its reference plane, units, bandwidth and processing. Corrected power, logarithmic level and a visibility threshold answer different questions. Keeping the definition consistent prevents an apparent disappearance from being interpreted without accounting for changed sensitivity or scaling.

RETAINED-RECORD REPROCESSING: Applying a changed correction or processing method to a preserved acquisition record while retaining the original data, both derived products and their processing identities. This comparison can explain a changed interpretation without treating it as a new physical observation. Independent validation remains necessary when the retained record helped select the new method.

Copyright 2026, James M. Atkinson

REVERSAL CHECK: A planned return from a modified setup to an earlier configuration to test whether the earlier response returns under comparable observation capability. It checks reversibility and can expose drift or state-history dependence. Reproducing the response does not by itself isolate which changed path caused it.

RUN-ORDER RANDOMIZATION: Assignment of feasible experimental configurations to acquisition order by a declared random procedure. It can reduce systematic association between a setting and unrelated temporal changes. It does not remove physical restrictions, relocking requirements or changing source behavior; those constraints and the actual order remain part of the diagnostic record.

SELECTION EFFECT: A change in the interpretation of evidence caused by how observations, tests or processing rules were chosen. Favorable tests selected after viewing outcomes cannot be treated as though they were the only predeclared possibilities. Preserve failed challenges, held-out records and the actual selection procedure when assessing what the evidence supports.

SHARED DEPENDENCY: A common clock, power supply, path, software component, calibration input or other influence linking nominally separate observations. It can preserve the same error across instruments or derived products. Counting labels or devices therefore does not establish the amount of independent confirmation.

Copyright 2026, James M. Atkinson

STATE-TRANSITION RECORD: A preserved record of the operation and timing by which the receiver moved between configurations, including any relock, impulse or recovery interval. It distinguishes transition behavior from settled behavior. Excluding a transient from a settled-state analysis does not remove its evidential relevance or justify deleting it.

TECHNICAL PEER REVIEW: Independent examination of the native data, configurations, calculations, calibration, challenge results and competing explanations supporting a finding. It tests the reasoning and evidence rather than merely approving a narrative. Unresolved disagreements lead to further measurements or explicit limitations, preserving the actual strength of the conclusion.

TEMPORAL CORRELATION: A relationship in the timing of observed events under a stated time basis and uncertainty. It can guide a causal investigation without proving its direction or mechanism. Shared control activity, instrument timing or another common cause must remain possible until discriminating evidence resolves those alternatives.

UNEXPLAINED SIGNAL: Observed component that survives initial validity checks but lacks sufficient evidence for source or functional attribution.

Kester, Walt. MT-080, Mixers and Modulators. Rev. 0. Analog Devices, October 2008. https://www.analog.com/media/en/training-seminars/tutorials/mt-080.pdf.

Annotation. Printed pages 1–2 and 5 support mixing terminology, dimensional scaling and image locations. The printed sine-product signs in equations (1)/(1a) on page 5 are not adopted; Model 4A independently derives its cosine-product law. No commercial performance inference is made. This instructional source treats modulation, frequency translation or receiver signal-chain operation through explicit physical relationships. Image frequencies, sidebands, local-oscillator injection and intermediate-frequency filtering have to be checked against the receiver's actual topology. Ideal mixer identities do not establish that a real component is free of compression, leakage, spurs or path-dependent calibration errors. Interpretation requires separating the publication's stated scope from the chapter's constructed experimental examples and their necessarily conditional conclusions.

Kester, Walt. MT-002, What the Nyquist Criterion Means to Your Sampled Data System Design. Rev. A. Analog Devices, October 2008. Pages 4–7 and 9–11. https://www.analog.com/media/en/training-seminars/tutorials/MT-002.pdf.

Annotation. Printed pages 4–7 and 9–11 support sampling and analog-band selection. The actual sample-rate, mixing and data-continuity conventions are those developed in Chapter 10, not a generic inference

Forensic use also requires retained acquisition metadata and a documented chain between the observed quantity and the conclusion ultimately reported.

Analog Devices. Specifications and Measurement of Local Oscillator Noise in Integrated Circuit Base Station Mixers. June 18, 2003. Mixer Noise Model and Effective Noise Floor of LO Driver. https://www.analog.com/en/resources/technical-articles/2022/07/16/08/18/specifications-and-measurement-of-local-oscillator-noise-in-integrated-circuit-base-station-mixers.html.

Annotation."Mixer Noise Model" supports the reciprocal-mixing mechanism inventory. Model 11B separately supplies its weighting, reference planes and premises; the chapter's challenge tests are applied synthesis rather than quoted universal receiver procedures. The technical treatment concerns the conversion of strong off-channel energy and local-oscillator phase noise into receiver degradation. An apparent rise in the noise floor can reflect oscillator-sideband mixing rather than increased external thermal noise or a new transmitter. Conclusions require blocker level, frequency offset, preselection, instrument state and phase-noise conditions at specified reference planes. The cited work is a methodological reference; the worked examples and the conclusions drawn from them remain separate authorial derivations requiring their own checks.

Volume Summary

Copyright 2026, James M. Atkinson

Define the question and the complete measurement chain

A receiver finding begins with a defined question, an authorized objective and a measurement quantity. Detection establishes that a stated criterion was met under the observed conditions. Classification, localization, device linkage and recovery of information require additional evidence. State the intended reference plane, frequency and time intervals, estimator and decision criterion before selecting a mode. This makes the later correction, uncertainty and challenge record intelligible to another examiner who was not present at the instrument.

The measurement chain includes the installed antenna, cables, adapters, filters, protection, gain stages, converters, clocks, sampling, software and stored representation. Each element can alter the signal, add a contribution or discard information. A calibrated scalar transfer can support an inverse calculation within its stated domain, while clipping, unknown automatic state or discarded data can defeat that inverse. Keep the raw indication and the ordered corrections, with their units and physical boundaries. Keep the result reversible to those declared inputs and states.

Configuration is therefore part of the measurement law. A requested gain, sample rate or filter setting is a command; its settled and valid state needs evidence. Preserve transition times, excluded intervals and the versioned corrections applicable to each accepted segment. Closing references test the functions they traverse at the time of the check. They can reveal a failure and guide investigation of an affected interval, but cannot by themselves prove uninterrupted validity throughout an earlier acquisition.

Copyright 2026, James M. Atkinson

Preserve the signal through gain, filtering and conversion

Sensitivity depends on the source plane, bandwidth, noise environment and decision procedure. The matched fixed-state cascade carries desired gain and added noise together. Early gain can reduce the input-equivalent effect of later noise, while preceding dissipative loss both attenuates and contributes thermal noise according to its temperature. The reference noise factor and actual signal-to-noise degradation answer related but different questions when the source temperature changes. Hot-cold inversion requires compatible gain, bandwidth, source temperatures and linearity in both states; its admissible ratio and conditioning are part of the calculation. Validate event detection separately in the intended environment.

Follow every important blocker as well as the desired signal. The first vulnerable stage may lose validity before a narrow downstream filter or display acts. Preselection can improve rejection while adding desired-path loss, and gain must fit between the noise-derived minimum and the downstream-loading maximum. An empty feasible interval calls for a changed architecture or operating condition. Input protection adds further distinctions among small-signal loss, leakage, survival and recovery. Use a weak reference and an observable-specific recovery criterion to identify intervals of impaired measurement after hardware survives.

Retain signed frequency, the selected conversion branch, loading and phase until a real representation requires folding. Images and spur lattices identify admitted possibilities, with amplitudes and coherent collisions requiring their own transfer and phase treatment. Filter skirts, ripple, group delay and ringing affect different observables. Automatic control introduces a

Copyright 2026, James M. Atkinson

trajectory whose calibrated state and sign must be retained through target changes. Detector takeoff, averaging law and recovery limits then determine what a displayed level represents. A narrow, stable trace can still carry the consequences of a broader or time-varying upstream path.

Copyright 2026, James M. Atkinson

Keep representation and estimator conventions explicit

Analog and digital demodulation are configured inferences from the retained waveform. The complex envelope distinguishes amplitude from phase and connects mean power to the actual averaging convention. Magnitude detection can lose an envelope reversal, and a phase derivative or finite difference requires a valid branch, nonzero signal where needed and explicit handling of resets. Frequency modulation, phase modulation and pulse observations therefore require appropriate bandwidth and time evidence. Intelligibility and waveform classification remain processing-dependent observations requiring further evidence for source and purpose.

For a digital quality metric, define the symbol experiment, reference, synchronization, alignment and normalization. A fit can remove effects that another question intends to measure, so retain its degrees of freedom and evaluate appropriate records outside the fitting set. Error-vector results and error counts also have different denominators and conditions. Rate accounting starts from declared finite populations: symbol opportunities, coded labels, information bits, complete frames and unique payload positions. Overheads act on their specified populations, mode changes require duration weighting, and retransmission or overlap does not create new delivered information. A stated rate is meaningful only with its count, wall interval and exclusions.

Spectral displays likewise depend on operations that need not commute. Averaging powers and averaging logarithmic levels yield different statistics. Resolution bandwidth, equivalent noise bandwidth and observation time have distinct roles. A finite Fourier analysis retains its actual samples,

Copyright 2026, James M. Atkinson

window convention and normalization; zero padding adds frequency-grid points without supplying new measured time history. Coherent amplitude, power density and integrated power need compatible scaling. Cross-spectral analysis additionally preserves channel order, conjugation and joint averaging. Shared noise or coherent cancellation requires examining the complex relationships and estimator assumptions before interpreting a scalar curve.

Copyright 2026, James M. Atkinson

Treat timing and acquisition integrity as part of the quantity

A software-defined receiver adds explicit numerical and data-path conventions. Mixing, filtering, decimation, channelization and quantization depend on ordering, state and scaling. Keep absolute sample indices, oscillator phase, filter history and valid output ranges through processing boundaries. Correct transforms still require the correct segment, binary-point interpretation and channel order. Executable identity, configuration, calibration and native format must remain connected to the record so that a second implementation can reproduce the same declared quantity instead of merely creating a similar-looking plot.

Clock accuracy, phase noise and multichannel alignment describe different aspects of timing. Initial epoch error, fractional-frequency offset and drift determine a deterministic time-error law within a stated interval. Physical delay has its own transfer-phase sign and wrapped-phase ambiguity. Integrated phase noise gives a band-limited timing RMS after a carrier-dependent conversion, while coherent power also depends on covariance and, for the exact Gaussian calculation, an additional distributional premise. Shared frequency does not establish aligned apertures, triggers or stored samples. Calibrate the actual boundaries and preserve discontinuities rather than forcing separately acquired segments into one coherent interpretation.

Coverage is determined by usable intervals and a declared event criterion. The timing model forms eligible event starts and merges their periodic union before calculating a probability under a justified phase distribution. Independent repeated trials require a separate assumption; a phase-locked event can repeatedly miss the same window. Verify the trigger at its actual

Copyright 2026, James M. Atkinson

processing location and retain valid pretrigger context. Sustained storage tests, sequence evidence and gap maps establish what was preserved. File hashes support later byte consistency, while continuity and actual coverage need their own acquisition evidence. Negative findings remain bounded by the tested bands, states, event classes and intervals.

Copyright 2026, James M. Atkinson

Calibrate the assembled result and retain its uncertainty

The installed receiving path belongs to the measurement. Antenna-terminal power and field strength are different measurands, and field conversion adds direction, polarization, loading, geometry and environment. Remote gain, bias delivery, cable routing and unused branches can alter noise, stability, mismatch or common-mode coupling. A conducted correction characterizes the path and conditions it actually measures. An optical or battery comparison may remove one coupling opportunity while changing gain, noise or sensitivity. Preserve the desired reference, assembly, state and corrections so each intervention remains interpretable.

Linearity and noise validity must also be maintained at the relevant signal levels. A local cubic model distinguishes per-tone powers, unequal products and extrapolated intercepts under stated loading. Source-generated products can contaminate the same observation, and formal extrapolation is not an attainable operating point. Reciprocal mixing instead depends on admitted blocker power and the oscillator phase-noise distribution weighted by the observation channel. A flat spectral shortcut, a noise subtraction or a remainder bound is valid only under its own premises. These mechanisms motivate different challenges and cannot be compressed into one universal dynamic-range score.

Calibration connects the scoped result to references and uncertainties, distinct from adjustment and verification. Signed corrections follow the physical path, and an uncertainty budget retains their dependencies rather than hiding configuration or implementation mistakes. Affine covariance propagation is exact with fixed coefficients and finite second moments; a

Copyright 2026, James M. Atkinson

nonlinear calculation requires attention to local adequacy, curvature and domain. Standard uncertainty is not a maximum error bound, and a coverage factor alone does not establish a probability guarantee. Apply the predeclared decision rule, allowing an indeterminate outcome when the available interval cannot settle the requirement.

Copyright 2026, James M. Atkinson

Earn the finding and preserve the accepted method

Locate candidate mechanisms in the architecture and predict their response to controlled changes. Preserve observation capability so a disappearance remains interpretable. A successful challenge can narrow alternatives while leaving source identity unresolved. When controls interact, observe the relevant combinations with a fixed response definition. Fresh acquisitions, run-order control and blocking address distinct limitations. Repeated plots, favorable coincidences and configuration labels cannot replace a missing physical comparison.

Reconcile timing, configuration and shared dependencies before combining domains. Instruments may share a clock or input path, and derived reports may use the same samples. Their agreement does not become independent by being counted twice. Report the observed consequences and remaining alternatives at the supported finding category. Numerical likelihoods require specified hypotheses and defensible data and selection models. Otherwise describe the discriminating evidence directly and identify the next useful test.

Link native data, configuration, corrections, uncertainty, coverage and inference in the final record. Preserve failed challenges, unknown intervals and alternatives for independent review. Changes to hardware, firmware, software or accessories trigger checks of the deployed method’s measurement functions. Retain the prior accepted state and explain revised derived results without rewriting observations. This record gives later examiners a reproducible basis for confirming, narrowing or correcting the conclusion as installations and software evolve.

EXPERT ROUNDTABLE

This expert roundtable comprises one hundred substantive discussions. Its preserved question numbering runs from 001 to 107, omitting identifiers 008–012, 015 and 032 by authorial direction. The reconstructed exchanges are fictional educational dialogue, not quotations from or authentic meetings of the deceased specialists. A populated question is not, by itself, proof that every technical calculation or cited source has passed independent publication review.

Moderator: Dr. James M. Atkinson

All historical contributor speech in recovered discussions is constructed pedagogical reconstruction. It must not be quoted as an authentic transcript of deceased participants. Technical case studies, calculations, and receiver examples are hypothetical unless the source explicitly establishes otherwise.

A recovered source establishes presence of substantial text. It does not independently establish that each numerical calculation, historical attribution, citation, or peer-exchange word minimum has passed a final whole-volume publication audit.

Roundtable question navigator

001. When may a receiver observation become an evidential claim?

002. How should the intended measurement determine the receiver architecture and its reference planes?

003. What must be preserved when a receiver changes state during an investigation?

004. When does agreement among receivers constitute independent corroboration?

005. What makes a receiver challenge test capable of revealing a material failure?

006. How should uncertainty, competing explanations, and decision costs govern the wording of a receiver finding?

007. When may observations, bearings, and timing evidence support localisation or attribution of an electromagnetic source?

013. What can preselection establish about the external origin of a spectral feature?

014. How should gain distribution be selected when strong signals coexist with weak emissions?

016. How can local-oscillator leakage and reciprocal mixing imitate or obscure emissions?

017. What does a receiver noise figure establish when the observed environment is not thermal noise?

Copyright 2026, James M. Atkinson

018. How should intermodulation products be challenged before calling a feature an emitter?

019. Where do analogue filtering and group delay distort the interpretation of short bursts?

020. How should an investigator validate a replacement receiver without losing comparability?

021. How should aperture jitter be budgeted at high input frequencies?

022. When does analogue front-end bandwidth invalidate an otherwise adequate sampling rate?

023. How can saturation and recovery effects create false pulse histories?

024. How should differential and integral nonlinearity enter a forensic uncertainty account?

025. What is lost when a converter clips, and what remains inferable?

026. When may dither improve a quantitative estimate without increasing intrinsic converter resolution?

027. How do converter interleaving mismatches create periodic spectral artifacts?

028. When is an effective-number-of-bits calculation relevant to an intermittent signal?

029. How should quantisation noise be distinguished from thermal and clock-related noise?

Copyright 2026, James M. Atkinson

030. What does calibration reveal about ADC performance across temperature and time?

031. When is bandpass sampling safe, and what must the analogue filter guarantee?

033. Which resampling operations preserve time, amplitude and phase claims?

034. What calibration is required for coherent time-interleaved digitisation?

035. How should polyphase channelisers be validated at channel boundaries?

036. When does decimation remove information that a later forensic question requires?

037. How may oversampling reduce in-band noise without increasing the independent information available?

038. How does finite word length change digital oscillator and filter behaviour?

039. Which apparent transient features can be created by sample-rate conversion?

040. How can the investigator reconcile different sampling clocks in one evidential timeline?

041. What do FFT resolution and bin spacing mean for a transient emission?

042. How do window functions trade leakage, resolution and amplitude bias?

Copyright 2026, James M. Atkinson

043. When does spectral averaging conceal short-lived signals?

044. How should overlapping windows affect counts of independent detection opportunities?

045. Which limits govern time-frequency localisation of a short burst?

046. What is the proper evidential use of multitaper and robust spectral estimates?

047. How can cyclostationary analysis help without manufacturing a unique device identity?

048. What does a matched filter actually test about an unknown waveform?

049. How should spectral occupancy be reported when observation is intermittent?

050. When are waterfall displays misleading representations of retained samples?

051. When must RF arrival time be separated from a software timestamp at the host?

052. How should traceability of frequency standards govern coherent captures separated in time?

053. When can oscillator disciplining conceal rather than correct a phase discontinuity?

054. How can common-reference distribution create correlated errors in supposedly independent receivers?

Copyright 2026, James M. Atkinson

055. Which observations discriminate clock drift, sample loss and delayed receiver buffering?

056. What can network time synchronisation establish about an RF acquisition chronology?

057. How do frequency-counter gate time and dead time bias observations of a drifting burst carrier?

058. What do phase-noise sidebands reveal about defects in an RF reference distribution network?

059. When is a spectrum analyser timebase adequate for multistation arrival-time localisation?

060. How can oscillator ageing be separated from thermal cycling in long-duration RF surveillance?

061. When do common-mode currents on coaxial screens imitate a spatially localised emitter?

062. Which near-field observations distinguish electric coupling from magnetic coupling in an enclosure?

063. What is missing when an antenna is calibrated exclusively under far-field conditions?

BIOGRAPHICAL DIRECTORY OF ROUNDTABLE CONTRIBUTORS

Eighty deceased historical specialists appear in this consolidated register: fifty-seven retained active contributors plus twenty-three newly nominated specialists whose topic assignments are documented in the developmental programme. No biography of moderator Dr. James M. Atkinson is included.

The biographies describe documented historical achievement and explain the limited relevance of that achievement to receiver engineering, signal analysis, mathematics or evidential evaluation. Every roundtable exchange is newly constructed pedagogical dialogue, not an authentic quotation, interview or meeting of these historical persons. Later technological developments are not imputed to them.

Editorial provenance: the fifty-seven earlier participant biographies are retained without rewriting; twenty-three new biographical accounts are interfiled alphabetically. Removed biographies exclusive to deleted discussions have not been restored. The new speakers are nominated only; their full dialogue remains unwritten.

Copyright 2026, James M. Atkinson

Contributors. Alphabetical register

Abraham Lempel

The historical record identifies Abraham Lempel (1936–2023) with lossless versus lossy representation, data complexity and reproducibility of retained digital evidence. An accurate professional description is an Israeli computer scientist and electrical engineer; co-developed Lempel-Ziv lossless compression.

Lempel developed compression methods which are mathematically reversible when their assumptions and coding rules are retained. For digital evidence the distinction between a lossless representation and a lossy transformation is decisive, particularly when subtle phase, amplitude or transient details may become important in a later investigation. A discussion within his expertise should ask for an unambiguous bit-exact reconstruction test and the exact coding state or dictionary rules used. The existence of a compressed file says nothing about its forensic fidelity unless the transform and verification evidence are preserved. This is a data-representation issue, not a claim that Lempel designed SDR recorders.

Within the new programme, Question 093 provides a suitable test of this expertise: Which RF phase and transient findings become untestable after lossy sample compression? The test design calls for the investigator to apply controlled bit-depth reduction and predictive compression to the same calibrated burst set, then compare recovered features. The possible error is straightforward: a saved image or lossy trace may be insufficient to re-examine a previously unknown modulation feature.

Copyright 2026, James M. Atkinson

Limits of attribution: His demonstrated authority lies in data compression and complexity, not in certifying a particular receiver or chain of custody. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Abraham Wald

Abraham Wald (1902–1950) developed mathematical statistics and statistical decision theory during a career that took him from European mathematical circles to Columbia University. His work is associated with sequential analysis and the sequential probability ratio test, in which evidence is assessed as observations accumulate rather than after an arbitrarily fixed number of samples. Wartime statistical research furnished important practical contexts for his examination of competing errors and decision rules. His death in 1950 places a clear chronological boundary on his experience: he could not have assessed digital receivers or the subsequent development of software-defined instruments.

In this roundtable Wald provides a rigorous standpoint for setting thresholds and interpreting an apparent success or failure. A spectrum monitor does not merely collect numbers; its decision procedure balances a probability of false alarm against the probability of missing a stipulated event. His work is especially pertinent when a test can be stopped as soon as a sufficient body of evidence has accumulated, or when the investigator changes the observation policy after several promising indications. Each of those choices alters the sampling and stopping model. The relevant subject is not a vaguely expressed desire for confidence, but the operating characteristics of a specified procedure under specified hypotheses.

Copyright 2026, James M. Atkinson

The editorial reconstruction confines Wald's contribution to statistical inference, experimental design and decision consequences. It does not present him as the inventor of receiver hardware or as an authority on modern spectrum-surveillance law. His historical research supports a demand for explicit null and alternative propositions, a declared sequence of permissible observations, and an explanation of the costs attached to mistaken conclusions. A forensic examiner can apply that discipline to receiver evidence while independently establishing the physical and electronic validity of each recorded sample.

Historical reference consulted: https://doi.org/10.1080/00031305.2025.2604805

Alan Mathison Turing

Alan Mathison Turing (1912–1954) was a British mathematician, logician and pioneer of theoretical computation. Born in London on 23 June 1912, he attended Sherborne School before winning a mathematics scholarship to King’s College, Cambridge. His paper of 1936, commonly identified by its title On Computable Numbers, introduced a mathematical account of effective calculation that subsequently became central to computer science. That work concerns the logical capabilities and limitations of procedures, rather than the electrical specifications of any modern receiver or analogue-to-digital converter. His significance for a discussion of digital measurement lies in disciplined separation of a formal algorithm from the physical assumptions under which its input is acquired.

During the Second World War Turing worked at the Government Code and Cypher School at Bletchley Park, contributing importantly to the cryptanalysis of Enigma traffic. His wartime role involved mathematical reasoning, electromechanical methods and careful operational testing, but

Copyright 2026, James M. Atkinson

it should not be recast as personal familiarity with present-day software-defined radios. He subsequently worked on automatic computing machinery and became associated with the development of early stored-program computing in Britain. In 1950 his paper Computing Machinery and Intelligence offered a famous argument about what could meaningfully be asserted of machine behaviour under an explicitly stated test.

In this constructed expert exchange, Turing's historical standpoint is represented as an insistence on the limits of inference from a digital representation. Quantising an observed analogue amplitude into a discrete code is a mapping, not a guarantee that the original physical state can be uniquely reconstructed. The biography does not imply that Turing made the words attributed to him in the fictional roundtable, nor that he derived the particular converter equations used here. The supporting Cambridge archival chronology establishes the principal dates and areas of work; the present engineering application is an editorial extrapolation and must be judged on its own mathematics.

Albert Abraham Michelson

Albert Abraham Michelson (1852–1931) was a physicist distinguished by precision optical measurement and experimental investigations of light. He developed interferometric methods in which coherent beams followed different paths before being recombined to reveal small differences of phase and length. His work won the 1907 Nobel Prize in Physics, the first physics Nobel awarded to an American. The historical context was the nineteenth- and early twentieth-century laboratory, with optical standards and mechanical adjustments rather than sampled complex waveforms or computer-controlled instruments.

Copyright 2026, James M. Atkinson

Michelson's proper connection to this roundtable is the difficulty of establishing an accurate measurement reference. Interferometry makes the phase consequence of a small path change visible and measurable, but the interpretation depends on coherent illumination, stable geometry and calibrated apparatus. The corresponding receiver question is not whether an SDR is an interferometer in the ordinary optical sense. It is whether a claimed phase difference or time-difference observation preserves the reference and stability requirements needed to compare distinct paths. Differential cable delay, clock wander, oscillator coherence and measurement-plane definition deserve scrutiny when an electromagnetic source is localised or when observations from separate receivers are combined.

His constructed peer contribution is therefore metrological, not an anachronistic judgement on particular digital converters. It asks which quantities were compared, what common reference was retained, and what systematic errors could move the apparent fringe or phase. A sharply presented spectral line can conceal substantial uncertainty in its physical origin, just as a beautifully resolved interference pattern is meaningful only under the conditions that produced it. Modern forensic conclusions must add their own uncertainty budget and evidence-preservation record; Michelson supplies the historical experimental sensibility, not that modern certificate.

Historical reference consulted: https://www.nobelprize.org/laureate/11

Andrey Nikolaevich Kolmogorov

Andrey Nikolaevich Kolmogorov (1903–1987) was a Russian mathematician whose work placed probability on an axiomatic foundation.

Copyright 2026, James M. Atkinson

His 1933 monograph formulated probability in terms of measure-theoretic principles and provided a coherent mathematical vocabulary for random variables, conditional expectations and events. He also contributed to stochastic processes, turbulence and mathematical analysis. This breadth matters because probability models are not ornaments attached to measurements after an experiment; they define what is being treated as random, what remains conditioned upon the observing procedure, and what conclusions can legitimately be drawn.

For receiver engineering, Kolmogorov's relevant intellectual domain is the stochastic interpretation of observed interference, noise and event arrivals. Noise samples may be uncorrelated under one model yet dependent under another; a nominally stationary process can cease to be so when a transmitter changes state or an automatic-gain loop adapts. Distinguishing an event probability from an empirical fraction of threshold crossings therefore requires a probability space, an observation mechanism and assumptions about temporal dependence. His historical work also encourages the separation of a mathematical proposition about random processes from physical evidence that the specified process describes the instrument and its environment.

The imagined questions assigned to him do not purport to reconstruct a lecture he gave on digitisation. They test whether analysts have defined the distributions and dependence structures implicit in statements such as 'independent detections' or 'white noise'. In the present roundtable, the force of Kolmogorov's work is to compel the author to name the assumptions under which confidence, variance or a false-alarm probability is calculated. Receiver circuits, calibration, antenna coupling and forensic

Copyright 2026, James M. Atkinson

attribution must still be established by their respective engineering and evidential methods.

Historical reference consulted: https://mathshistory.st-andrews.ac.uk/Biographies/Kolmogorov/

Antony Hewish

Antony Hewish (1924–2021) enters the discussion on the strength of a recorded career as a British radio astronomer; scintillation arrays and the pulsar discovery programme. This context is materially connected to short transient detection, array methods, propagation effects and the interpretation of weak radio events.

Hewish's radio-astronomy research involved antennas and analysis designed to reveal rapidly varying, weak radio phenomena. His connection to a rare-emission survey is therefore stronger than a superficial analogy to stars. In the subject-specific case, the moderator may ask how an intermittent astronomical signal is distinguished from environmental interference, how array geometry affects sensitivity and whether the receiving schedule creates a spurious periodicity. The experiment ought to preserve individual observation times and detector settings. Such a contribution can illuminate the difficulty of transients without suggesting that astronomical pulsars are covert radio transmitters.

Question 064 is the most direct illustrative assignment, asking: How should polarisation mismatch and pattern nulls qualify a negative surveillance search? Its recommended measurement challenge is to rotate a calibrated test emitter through orthogonal polarisations and map missed detections across a surveyed room. The author must recognise the counterexample: a clear display in one antenna orientation cannot certify the absence of an emitter with a different polarisation.

Copyright 2026, James M. Atkinson

Any proposed attribution must survive the challenge that a clear display in one antenna orientation cannot certify the absence of an emitter with a different polarisation. The chosen scholarly intervention has value only insofar as short transient detection, array methods, propagation effects and the interpretation of weak radio events supplies a relevant explanation.

Limits of attribution: His historical research is particularly appropriate for transient-source discrimination, not the identification of contemporary commercial emitters. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Arthur Edwin Kennelly

Arthur Edwin Kennelly (1861–1939) was an electrical engineer whose professional life connected cable telegraphy, alternating-current theory and the teaching of electrical engineering. Born near Bombay in British India and educated principally in Europe, he worked in electrical communication before becoming associated with leading engineering research and instruction in the United States. He is particularly relevant to the development and practical use of complex impedance, alternating-current circuit concepts and the analysis of transmission systems. His era preceded electronic sampling, but not the fundamental problems of loading, loss, reflection and the difference between a circuit model and a real connection.

Kennelly's role in this book is sharply physical. A receiver does not observe an antenna signal in isolation from conductors, grounding arrangements and the impedance of the devices to which it is connected. A nominal fifty-ohm termination, for example, can be a useful reference

Copyright 2026, James M. Atkinson

convention while still leaving uncertainties in connectors, common-mode paths and frequency-dependent matching. The investigator who removes an antenna or substitutes a termination is performing a challenge to a particular coupling mechanism, not a universal proof that every remaining signal has an internal origin. Such questions are natural extensions of classical electrical-network reasoning.

In constructed dialogue Kennelly may appropriately challenge a claim about reference planes, line conditions or the diagnostic meaning of a terminated port. He is not represented as having known the architecture or firmware of twenty-first-century software-defined radios. His authority is confined to the documented electrical principles that survive changes in technology. The modern examiner remains responsible for measuring actual network properties, recording configuration changes and distinguishing a calculated transmission relationship from verified behaviour in the field.

Historical reference consulted: https://doi.org/10.1093/ref:odnb/45958

Bertrand Russell

Bertrand Russell (1872–1970), the British philosopher, mathematician and public intellectual, was educated at Trinity College, Cambridge. His collaboration with Alfred North Whitehead on Principia Mathematica belongs to a sustained programme in the logical foundations of mathematics. His wider philosophical writing examined knowledge, language, inference and the limits of apparently self-evident propositions. He was not a radio-receiver designer, and his substantial political and literary activities must not be mistaken for specialist training in electromagnetic measurement.

Copyright 2026, James M. Atkinson

Russell is present here because an expert witness can slide from a precisely defined observation into a far stronger assertion while using the same persuasive vocabulary. If a spectrum analyser reports a peak, the proposition 'the selected estimator exceeded its threshold' is not logically identical to 'a particular transmitting device was present'. Additional premises about front-end integrity, interference, timing, signal classification and source identity are required. Russell's concern with logical form offers a valuable editorial test: identify the premises, distinguish necessary from sufficient conditions, and determine whether the conclusion is stronger than the evidence permits.

His reconstructed exchanges thus examine the grammar of technical argument rather than pretending to deliver nineteenth- or twentieth-century radio laboratory testimony. A formally valid deduction can still rest on a false engineering premise; conversely, a useful engineering indication may remain too weak for the specific forensic conclusion desired. Russell's presence helps maintain that separation. He would not be quoted as authorising any specific modern test protocol, threshold, legal conclusion or software implementation. Those matters belong to contemporary standards, measurements and properly attributed expert analysis.

Historical reference consulted: https://russell.humanities.mcmaster.ca/about-russell/russells-life/

Charles Hard Townes

The historical record identifies Charles Hard Townes (1915–2015) with spectral purity, quantum resonance, high-frequency measurement and the relationship between oscillator physics and signals. An accurate professional description is an American physicist; maser and laser research, Nobel Prize in Physics 1964.

Copyright 2026, James M. Atkinson

The maser supplies a historically grounded example of highly selective electromagnetic oscillation. Its significance for this volume lies in the physics of coherence, spectral purity and measurements whose interpretation depends on the reference oscillator. A suitable question might ask how additive noise from a distribution amplifier differs from intrinsic oscillator fluctuations, and what phase-noise sideband measurements can actually establish about their origin. Such debate should state the instrument noise floor, carrier power, offset frequency and any simultaneous supply perturbation. Townes would contribute resonance physics rather than an invented analysis of later SDR software.

Within the new programme, Question 054 provides a suitable test of this expertise: How can common-reference distribution create correlated errors in supposedly independent receivers? The test design calls for the investigator to inject a known correlated perturbation and compare outcomes under one shared reference, separated references and cross-reference switching. The possible error is straightforward: agreement between receivers supplied by the same defective reference is not independent corroboration.

The intended teaching purpose is to illuminate partition shared clock-tree noise, correlated supply disturbances, cable dispersion and true antenna-channel phase variation. without blurring the quite different historical evidence concerning spectral purity, quantum resonance, high-frequency measurement and the relationship between oscillator physics and signals.

Limits of attribution: His direct historical contributions concern masers, spectroscopy and related instrumentation, rather than all present-day

Copyright 2026, James M. Atkinson

phase-noise test procedures. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Charles Proteus Steinmetz

Charles Proteus Steinmetz was born in Breslau in 1865 and died in 1923. An engineer and mathematical analyst whose career became closely associated with the development of alternating-current power systems in the United States, he contributed substantially to the practical theory of electrical circuits and magnetic phenomena. After emigrating to the United States, he joined General Electric in Schenectady and helped develop mathematical methods which made complex alternating-current relationships easier to calculate and engineer. The National Inventors Hall of Fame records his work on alternating-current technology, magnetic hysteresis and the wider advancement of electrical engineering. His career demonstrates the close partnership between analytical models and the physical impedances, losses and operating conditions of actual equipment.

In this hypothetical roundtable Steinmetz challenges the assumption that a static gain correction adequately describes a converter surrounded by frequency-dependent analogue circuitry. That concern is historically aligned with his expertise in network behaviour and alternating-current analysis. It does not imply familiarity with a modern switched-capacitor converter or digital signal-processing software. The intended educational value is to extend the questions of loading, phase, transient response and material-dependent losses into a contemporary measurement problem while keeping the modern technical details plainly identified as the present author's construction. His biography also illustrates why apparently small

Copyright 2026, James M. Atkinson

changes in electrical configuration may be material to a claimed calibration: a system is defined by its network of interacting components rather than by the most conveniently isolated device in its schematic. His constructed intervention also emphasises that a calibration is a measurement of relationships within a network, not a permanent property of a single isolated component.

Charles Sanders Peirce

Charles Sanders Peirce (1839–1914) combined work in logic and the philosophy of science with practical experience in geodesy, gravimetry, spectroscopy and scientific measurement. His long association with the United States Coast Survey furnished a setting in which instrumental observations, errors and physical standards had practical consequences. He became a major figure in the development of pragmatism and in the analysis of signs and inference, notably the movement between observation, explanatory hypothesis and experimental test. This breadth makes him a more specifically relevant experimental thinker than a generic commentator on truth.

The technical-surveillance investigator repeatedly faces an abductive problem: a spectral feature might arise from an external emitter, a receiver-generated image, mixing in an overloaded stage or some ordinary environmental system. Peirce's treatment of explanatory reasoning is useful for asking how one proposes a hypothesis that accounts for a striking observation without treating the proposal as proof. The hypothesis gains force when it yields discriminating predictions that rival mechanisms do not share, and when those predictions survive a suitably documented challenge. For example, a preselector change, receiver substitution or controlled

Copyright 2026, James M. Atkinson

injection can test a proposed signal path, although none is decisive without considering its own instrumental dependencies.

The imaginary roundtable does not imply that Peirce encountered an SDR, performed spectrum-forensic casework or endorsed contemporary legal practice. It makes limited use of his documented work in inference and measurement. His biography also reminds readers that logic and metrology have a common discipline: observations need provenance, hypotheses need explicit content, and the investigator must keep the difference visible in the written conclusion. Such a role respects his historical career while offering an appropriate philosophical challenge to engineering overstatement.

Historical reference consulted: https://plato.stanford.edu/entries/peirce/

Christiaan Huygens

Christiaan Huygens (1629–1695) was a Dutch mathematician, physicist, astronomer and inventor associated with foundational work on pendulum motion, improved timekeeping and the wave theory of light. He developed practical pendulum clocks and investigated the theoretical relation between an oscillator's geometry and its period. His astronomical work included observations of Saturn and the improvement of optical instruments. These accomplishments belong to the seventeenth century, long before electronic oscillators, quartz frequency standards or digital sample clocks, yet they illuminate enduring problems in timing and phase.

The immediate relevance of Huygens to receiver measurement is the distinction between a mathematical period and a clock's realised performance. An ideal periodic model contains no environmental drift; a physical oscillator responds to mechanical, thermal and other disturbances. Modern multisite time-difference measurements similarly require the

Copyright 2026, James M. Atkinson

investigator to distinguish a nominal sample rate from actual clock phase, an indicated timestamp from a radio-frequency arrival time, and common triggering from independent frequency stability. Huygens's work does not supply the mathematics of present-day disciplined oscillators. It illustrates why the behaviour of the timekeeper must be measured rather than taken for granted.

His participation is a deliberately constructed historical perspective, not a claim that he discussed radio surveillance or stochastic clock-noise spectra. The commentator may reasonably ask what period has been defined, how it has been compared, and what observational evidence supports a timing relationship. Contemporary contributors to the argument must then provide phase-noise models, calibration certificates and uncertainty propagation. In this narrow role the older history of clocks and waves enriches the engineering discussion without assigning impossible twentieth-century knowledge to its speaker.

Historical reference consulted: https://mathshistory.st-andrews.ac.uk/Biographies/Huygens/

Claude Elwood Shannon

Claude Elwood Shannon was born in Michigan in 1916 and died in 2001. He completed undergraduate studies in mathematics and electrical engineering at the University of Michigan and graduate work at the Massachusetts Institute of Technology, including a doctorate in 1940. His work on switching circuits and his 1948 mathematical treatment of communication became central contributions to their respective disciplines. MIT's institutional obituary documents his education, his academic career, and his long association with communications research. The form Dr Shannon is supported by that record. [B03]

Copyright 2026, James M. Atkinson

In this roundtable, Shannon's constructed role concerns the relation between a retained representation and the distinctions required by a later analytical question. It is not a biographical claim that he anticipated the particular storage systems, acquisition metadata, or forensic workflows used as modern examples. Those examples are introduced to test a general reasoning discipline: a record's size, numerical word length, and visual richness do not by themselves establish that it preserves the information needed for a proposed inference. The principal response follows the physical and sampling boundaries established by the preceding speakers.

The editorial purpose is also to prevent information-theoretic language from becoming an unqualified promise of recovery. Where a transformation has discarded distinctions, a documented calculation cannot simply recreate the missing observations. Conversely, a carefully selected representation can support a useful restricted claim without preserving every possible property of the input. The dialogue examines that choice through retention, processing provenance, and the difference between discovery and later reanalysis. Readers should distinguish this present application from Shannon's published historical work. His documented expertise justifies the perspective; the supported signal model and the actual acquisition determine whether any specific modern claim succeeds.

Historical expertise and source concordance: Information theory, communication limits and Boolean switching theory. Data loss and non-invertible observations fit his documented mathematical field, while attribution of specific modern receiver designs would exceed that evidence. Independent historical source: https://www.itsoc.org/about/shannon

David George Kendall

David George Kendall (1918–2007) was a British mathematician and a leading figure in applied probability. Born in Ripon, Yorkshire, he performed

Copyright 2026, James M. Atkinson

wartime scientific work before becoming associated with Oxford and, subsequently, the University of Cambridge, where he held a professorship in mathematical statistics. His research encompassed queueing systems, branching processes, stochastic modelling and geometrical probability. The best-known queueing notation bearing his name is a reminder that observable events can arise from systems with distinct arrival and service characteristics rather than from a single stationary Bernoulli mechanism.

Kendall is useful in a technical-surveillance discussion whenever emissions arrive irregularly or when acquisition opportunities are separated by receiver retuning, scanning or data-retention schedules. A monitor can see many threshold crossings during one prolonged transmission, then miss a sequence of short transmissions during an unobserved interval. These counts do not automatically give independent trials. Mathematical models of arrivals, event durations and service or dwell time can make the investigator's assumptions explicit. A well-posed probability problem distinguishes elapsed time, valid exposure time, the number of distinct events and the chosen sampling process.

The historical Kendall did not design modern SDR monitoring software. His fictional peer intervention should therefore challenge the probabilistic assumptions underlying occupancy estimates and missed-event claims, while leaving hardware claims to physical evidence. An effective answer would show why the proposed acquisition schedule represents the relevant population and how dependence affects uncertainty. The contribution provides a precise intellectual counterweight to the attractive but unsupported practice of dividing alarm counts by wall-clock duration and presenting the result as a transmitter's actual duty cycle.

Historical reference consulted: https://mathshistory.st-andrews.ac.uk/Biographies/Kendall/

David Harold Blackwell

David Harold Blackwell (1919–2010) was an American mathematician and statistician whose contributions extended across probability, game theory, information theory and Bayesian inference. He taught at Howard University before joining the University of California, Berkeley, where he became an influential member of the statistics faculty. His career also illustrates the institutional obstacles encountered by Black scholars in twentieth-century American mathematics. His historical research included decision problems and the comparison of statistical experiments, providing a distinctive point of entry to arguments about whether a measurement procedure retains sufficient information for a proposed decision.

Blackwell's contribution to this roundtable concerns the informativeness of competing observations. A broadband recording and a narrowband, thresholded alarm may be derived from the same physical signal yet support different classes of later inference. A summary statistic can be adequate for a specified decision without retaining everything needed for a different question. Similarly, combining two detector outputs does not necessarily yield independent evidence, especially when they share an antenna, front end or decision logic. His tradition encourages the examiner to describe exactly what decisions can be justified from the retained observation and what information a processing stage has erased.

The imaginary dialogue does not attribute to Blackwell the invention of any particular receiver circuit or test instrument. It draws upon his demonstrable work on information and decision theory while acknowledging that contemporary RF engineering supplies the physical

Copyright 2026, James M. Atkinson

model. Forensic reports should therefore distinguish relative statistical informativeness from metrological validity. A mathematically more informative record can still be corrupted by overload or timing error, just as a perfectly calibrated receiver can retain too little information to answer the later forensic question.

Historical reference consulted: https://mathematics.howard.edu/articles/david-harold-blackwell-1919-2010

David Lennox Mills

David Lennox Mills (1938–2024) was an American computer engineer; creator of Network Time Protocol. The contribution relevant to this manuscript is network clock synchronisation, packet timing, host time, error budgets and protocol assumptions.

He developed the Network Time Protocol to address the difficulty of coordinating distributed computer clocks over networks with variable packet delays. That problem is close to, but not identical with, RF time-of-arrival measurement. A useful reconstructed exchange would force the moderator to separate a device clock, a network-disciplined operating-system clock and the timestamp associated with an analogue sampling aperture. Path asymmetry, queueing delay and host scheduling can produce timestamp changes without an RF event moving. Mills is well suited to challenge unjustified precision claims for software logs and to specify what a better trace would contain.

In the planned Question 051, the concrete issue is: When must RF arrival time be separated from a software timestamp at the host? An appropriate proposed experiment is to inject a calibrated simultaneous pulse into an RF input and an independently time-tagged reference path; measure the

Copyright 2026, James M. Atkinson

latency distribution and its drift under processing load. The corresponding interpretive caution is that a timestamp generated when a buffer is written can be repeatable yet systematically late relative to arrival at the antenna.

Limits of attribution: He is authoritative on network time and system chronology, but network timestamps are not automatically RF arrival time and must not be portrayed as such. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

David Slepian

David Slepian was an American mathematician whose research career at Bell Laboratories involved information theory, coding and finite-record spectral concentration. Biographical information maintained by the IEEE Information Theory Society identifies his training at Michigan and Harvard, military service during the Second World War, and research appointments that preceded his long Bell Laboratories career. His contributions were recognised through awards in information theory and related mathematical fields. The discrete prolate spheroidal sequences associated with his name provide a foundation for understanding how a finite data sequence can concentrate energy in an explicitly defined frequency region. The relationship between this mathematics and multitaper spectral estimation is documented in modern scientific computing references. [R1, R5]

His relevance to the present discussion is methodological rather than historical testimony. A modern investigator may obtain multiple concentrated spectral estimates from the same physical acquisition, but

Copyright 2026, James M. Atkinson

mathematical orthogonality does not itself establish independence of electromagnetic sources or of the receiver's errors. The scholarly persona used here reasons from Slepian's concentration framework to contemporary forensic questions concerning false negatives, shared instrument paths and the retention of raw complex samples. Those hypothetical cases were not experiments undertaken by Slepian, and no constructed speech should be attributed to him as a historical quotation. His work is represented as an intellectual precedent for disciplined spectral estimation, not as an endorsement of any modern surveillance apparatus or its claimed sensitivity.

The distinctive merit of this analytical tradition is that its boundary conditions can be stated and challenged. That quality is particularly important when a forensic laboratory moves from a mathematical claim about leakage to a physical claim about the presence or absence of a transmitter. The two inferences require different validation, even when they share the same retained data.

Historical expertise and source concordance: Bell Laboratories researcher in information theory, prolate spheroidal wave functions and signal concentration. Relevant to spectral-estimation conversations, with no assertion of knowledge of later field SDR systems. Independent historical source: https://www.itsoc.org/profile/8962

Dennis Gabor

Dennis Gabor was born in Hungary in 1900 and died in 1979. The American Institute of Physics archival catalogue identifies his papers and their coverage of electron optics, communication theory, information theory, holography, and work associated with Imperial College. Imperial's archival description likewise records his teaching and research papers and the documentation of his Nobel Prize. These institutional records support

Copyright 2026, James M. Atkinson

the description of a Hungarian-born physicist working in Britain and the academic form Professor Gabor. This account does not assign an unsupported citizenship date or extend his historical work into an endorsement of contemporary receiver software. [B10, B10a]

Gabor's constructed peer question concerns the representation of a transient. A chosen analysis interval, window, or display convention can emphasise one property while obscuring another. The modern example asks how an examiner can compare several valid views without selecting only the one that favours a preferred explanation. His documented interests in communication and the representation of signals supply the basis for that perspective. The present acquisition examples and proposed reporting rules are newly authored, not historical quotations.

The exchange is intended to preserve both analytical flexibility and evidential discipline. Reanalysis can be valuable when the source observations survive and the transformation is explicit. Its usefulness does not justify silently replacing a declared confirmatory procedure with an exploratory setting chosen after the event. Gabor's question therefore asks what the report should retain: not an indiscriminate gallery of displays, but the relation between each view, the property it estimates, and the reason for comparing it with another. The resulting distinction is important for burst timing, spectral discrimination, and the separation of physical duration from display persistence. His contribution remains bounded by those methodological and signal-representation concerns.

Historical expertise and source concordance: Communications representation, time-frequency analysis, electron physics and holography. His historical work supports interrogation of transient localisation and finite observation; modern FFT implementation details are editorially constructed.

Independent historical source: https://catalogues.royalsociety.org/CalmView/Record.aspx?id=NA6123&src=CalmView.Persons

Donald Watts Davies

The historical record identifies Donald Watts Davies (1924–2000) with packet timing, networking state, reproducibility of message chains and digital infrastructure. An accurate professional description is a Welsh computer scientist; packet switching at the UK National Physical Laboratory.

Davies helped establish packet switching as an efficient method for sharing communications infrastructure. Packet ordering and variable delay matter to a multireceiver system when digital samples pass through host queues, interfaces or networks before their final archival timestamp. A proposed exchange would compare time of RF acquisition with time of packet transport, asking which header values belong to which events and which delays remain unobserved. He is appropriately linked to network architecture, queueing and documentation. The moderator must keep RF phase measurements in the remit of frequency and receiver specialists.

Within the new programme, Question 056 provides a suitable test of this expertise: What can network time synchronisation establish about an RF acquisition chronology? The test design calls for the investigator to capture the same calibration event with hardware timestamps while changing upstream network delay asymmetry and logging system clock steps. The possible error is straightforward: a narrow network-time offset estimate does not bound unmeasured analogue group delay.

The intended teaching purpose is to illuminate explain network offset estimation, asymmetrical delay, server hierarchy, host-clock corrections and why synchronised log time is not automatically rf sample time. without

Copyright 2026, James M. Atkinson

blurring the quite different historical evidence concerning packet timing, networking state, reproducibility of message chains and digital infrastructure.

Limits of attribution: His authority concerns communication systems and packet networks; conclusions about RF front-end physics require additional specialists. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Edsger Wybe Dijkstra

Edsger Wybe Dijkstra (1930–2002) enters the discussion on the strength of a recorded career as a Dutch computer scientist; algorithms, program correctness and systems reasoning. This context is materially connected to concurrency, deterministic processes, implementation assurance and reproducibility of digital acquisition.

Dijkstra's methods of programming and algorithmic correctness support a crucial distinction between logical ordering and physical measurement time. A receiver may process queued samples in a correct computational order while still assigning the wrong arrival-time semantics to its outputs. His contribution could examine invariants linking sample indexes, buffer boundaries, timestamps and explicit invalid intervals. A proof that software runs correctly under one implementation does not certify analogue capture latency, yet it can expose hidden assumptions about state and reproducibility. That boundary makes him a defensible participant in SDR software provenance discussions.

Copyright 2026, James M. Atkinson

Question 055 is the most direct illustrative assignment, asking: Which observations discriminate clock drift, sample loss and delayed receiver buffering? Its recommended measurement challenge is to introduce independent perturbations of clock frequency, simulated packet loss and host load, then measure distinct residual signatures. The author must recognise the counterexample: a gap in displayed time does not prove an RF emitter ceased transmitting.

Any proposed attribution must survive the challenge that a gap in displayed time does not prove an rf emitter ceased transmitting. The chosen scholarly intervention has value only insofar as concurrency, deterministic processes, implementation assurance and reproducibility of digital acquisition supplies a relevant explanation.

Limits of attribution: He is valuable for software invariants and the separation of logical from physical time, not for unverified analogue receiver performance claims. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Edward Weston

Edward Weston was born in Wolverhampton, England, and moved to the United States in 1870. His engineering work connected materials, electrical instrumentation, and practical measurement. The National Inventors Hall of Fame records his development of stable-resistance alloys and accurate portable electrical instruments, including the direct-reading portable voltmeter associated with his induction. His work belongs to the physical construction of measurement systems, not to the later digital receiver

Copyright 2026, James M. Atkinson

technologies discussed in this volume. The biographical dates and the English-to-American career description are supported by that institutional record; no unsupported doctorate or citizenship date is assigned here. He is addressed as Mr Weston. [B01]

Weston's selection as the first principal respondent is an editorial decision grounded in that measurement expertise. His constructed role concerns the relation between a reference, the instrument that carries a comparison, and the quantity reported at a declared boundary. That role permits useful questions about loading, connection changes, transfer corrections, and the distinction between a stable indication and a valid physical measurement. It does not imply that Weston historically devised the modern logging or validation procedures placed in his dialogue. Those applications are newly authored and are supported separately by the volume's receiver-system discussion.

The contribution is deliberately narrower than a general authority over every part of an SDR. Weston establishes the physical comparison that later speakers test from sampling, informational, statistical, and methodological perspectives. This separation prevents the historical name from becoming a substitute for the modern technical evidence. Readers should assess the proposed experiments and their assumptions on their merits, while using the biography to understand why this particular historical perspective has been included. His place in the discussion is that of a measurement engineer whose documented work makes the opening boundary intelligible.

Historical expertise and source concordance: Electrical instruments and precision measurement, including portable voltmeters and resistance alloys; not a historical radio-Forensics practitioner. Independent historical source: https://www.invent.org/inductees/edward-weston

Copyright 2026, James M. Atkinson

Edwin Howard Armstrong

Edwin Howard Armstrong (1890–1954) was an American radio engineer whose work was associated with Columbia University. His historically documented areas of work include regenerative reception, superheterodyne conversion, and wideband frequency-modulation practice. The relevance of that intellectual tradition to this textbook is interpretive rather than personal: no historical endorsement, eyewitness evidence, modern SDR testing, or authenticated quotation is attributed to him. The constructed discussions draw upon this methodological background while evaluating contemporary hypothetical instrumentation. In particular, the associated questions 013, 016, 018, 022, 023, 031 explore mechanisms and evidence in which conducted attenuation measured between two coaxial ports is not automatically radiated-source isolation in a populated equipment room. The panel uses his named contribution to ask a specific and falsifiable question: how should an investigator test actual mixer behaviour, oscillator products and interference rather than merely a final detector trace? To answer responsibly, one must examine S21, S11, input compression, insertion loss, coaxial common-mode current, and displayed spur level, rather than treating the apparatus readout as a self-authenticating account of physical origin. One illustrative circumstance is that the feature weakens after the filter is substituted, although an external radiator, a mixer image, and ingress through the shield of the feeder remain possible. A competing interpretation is that an out-of-band blocker drives a nonlinear stage, while imperfect connector shielding offers a path which bypasses the nominal filter response. This contrast should be tested by introduce a level-verified signal ahead of the antenna connector, interchange the filter with a

Copyright 2026, James M. Atkinson

matched dummy section, and repeat with a terminated rf port, with adverse observations and calibration states preserved. The biographical facts establish professional chronology and domain of scholarship; the imagined question and answer are editorial devices used to teach the distinction between direct observation and model-dependent inference. No claim is made that the individual employed, approved, or could have anticipated the exact modern instrumentation named in this educational exercise. The reader must rely on the measured variables, explicit assumptions, and the validity of the controlled comparison rather than on the prestige of the historical contributor.

Historical expertise and source concordance: Regenerative and superheterodyne receiver engineering and wideband frequency modulation. Attribution is appropriate for RF-stage mixing, gain, receiver images and overload, but not for personal knowledge of later digital-forensics protocols. Independent historical source: https://www.ee.columbia.edu/content/edwin-howard-armstrong

Egon Sharpe Pearson

Egon Sharpe Pearson was born in Hampstead in 1895 and died in 1980. University College London's archival account records his education at the Dragon School, Winchester College, and Trinity College, Cambridge, followed by his appointment at UCL. He became Professor of Statistics in 1935. The same record describes his collaboration with Jerzy Neyman on hypothesis testing and with Walter Shewhart on statistical methods in industrial production. It also records his presidency of the Royal Statistical Society and election to the Royal Society. Professor Pearson is therefore a supported form of address. [B11]

His peer question examines a practical complication in the boundary between development and validation. A receiver may legitimately adapt its

Copyright 2026, James M. Atkinson

threshold as part of a fixed procedure. Testing only a constant threshold would then test a different system, while allowing unrestricted changes after observing results would compromise the interpretation of validation. Pearson asks the principal respondent to distinguish these situations and to confront the possibility that a precisely implemented adaptive rule operates outside the background model supporting its claimed performance.

This is a newly authored receiver application, not a statement that Pearson evaluated the contemporary systems described. The historical connection lies in his documented testing and industrial-statistics work. His role gives the discussion a concrete challenge: what exactly is frozen, what is allowed to change, and which observations show that the resulting procedure meets the intended claim? The exchange also addresses the preservation of reference membership, threshold history, and shared dependencies. Its purpose is not to reject adaptation, but to prevent the adjective adaptive from obscuring an undefined experiment. The biography and role together explain why a statistical collaborator is needed to question the principal answer rather than merely repeat its conclusions.

George Ashley Campbell

George Ashley Campbell (1870–1954) was an American electrical engineer who helped develop the mathematical theory and practice of long-distance telephone transmission. His work on loading coils and electric wave filters arose from the need to transmit many telephone conversations over long circuits while managing attenuation and interference. The National Inventors Hall of Fame identifies him with early wave-filter development and the engineering applications of mathematical transmission theory. His

Copyright 2026, James M. Atkinson

contribution is therefore relevant to the origins of frequency-selective networks, not merely to the later terminology of digital filtering.

Campbell's practical significance to an SDR roundtable lies before the analogue-to-digital converter. A preselector, transformer, cable or filter gives the receiver a frequency-dependent and load-dependent view of the external environment. That view changes when the signal path is substituted, terminated or retuned. Filter rejection of a strong adjacent signal may be essential to preventing a mixer or amplifier from producing a spurious in-band product. Conversely, an erroneously matched or insufficiently characterised filter may attenuate the very emission that an investigation seeks to detect. Such observations cannot be reduced to a nominal bandwidth value printed on the instrument front panel.

The reconstructed speaker may be asked to distinguish desirable passband behaviour from achieved performance and to analyse the consequences of cascading sections. He is not represented as a modern RF surveillance operator or the designer of contemporary software architectures. The limits of his historical competence are those of classical transmission and filter engineering, which remain necessary elements of the complete measurement chain. His inclusion encourages genuine circuit-level challenge tests, not an anachronistic claim that old network theory alone establishes the identity of a present-day source.

Historical reference consulted: https://www.invent.org/inductees/george-ashley-campbell

George Edward Pelham Box

George Edward Pelham Box (1919–2013) was a British-born statistician whose career spanned industrial experiment, quality engineering, time-series modelling and academic research in the United States. During the

Copyright 2026, James M. Atkinson

Second World War, practical measurement problems encouraged his development as a statistician. He subsequently became strongly associated with the design and analysis of experiments and with the investigation of processes that change over time. The University of Wisconsin was an important centre of his later research and teaching. His work is unusually well suited to a discussion of experiments that are designed to expose the causes of a receiver anomaly.

An RF investigator may propose changing an antenna, gain level or preselector to see whether a suspicious spectral feature moves or disappears. Box's experimental tradition asks whether that intervention is properly isolated and whether the resulting interpretation confuses a changed cause with a changed measurement system. Factorial designs, controlled replication and examination of interactions offer alternatives to an improvised sequence in which several receiver settings are altered together. His time-series work is likewise relevant to drifting backgrounds, periodic disturbances and the possibility that a process has changed regime during the investigation.

This editorial reconstruction is careful not to make Box a source of specific modern SDR instrument specifications. His role concerns experimental thinking, model criticism and the interpretation of repeated measurements. If a proposed factor is confounded with temperature, retuning or operator selection, the results need qualification even when the resulting graph looks impressive. The central lesson is practical: the best experiment is one in which competing mechanisms make distinguishable predictions, and the record preserves the actual design rather than a retrospective account tailored to the most striking result.

Grace Brewster Murray Hopper

The historical record identifies Grace Brewster Murray Hopper (1906–1992) with software reproducibility, machine representation, program versions and documentation necessary for independent examination. An accurate professional description is an American computer scientist and United States Navy officer; compiler and programming-language pioneer.

Hopper helped make computing programs reproducible, inspectable and maintainable across increasingly complex systems. A modern SDR receiver can retain identical raw samples while producing different classifications under changed source code, firmware, dependency versions or data-type handling. Her contributions to programming systems justify a rigorous discussion of build records, configuration manifests, deterministic transformations and the distinction between data integrity and algorithmic correctness. It would be inappropriate to present her as a witness to present-day FPGA products, but fitting to apply her systematic approach to the documentation and independent reconstruction of acquisition software.

Within the new programme, Question 090 provides a suitable test of this expertise: How can a surveillance report avoid unnecessary communication-content collection? The test design calls for the investigator to compare a privacy-minimising triggered metadata record with a full-IQ recording for the stated detection task. The possible error is straightforward: more retained information is not automatically necessary, proportionate or probative.

Copyright 2026, James M. Atkinson

The intended teaching purpose is to illuminate distinguish energy and timing metadata, spectrum occupancy, publicly specified physical-layer fields and the acquisition of private payloads. without blurring the quite different historical evidence concerning software reproducibility, machine representation, program versions and documentation necessary for independent examination.

Limits of attribution: She is not depicted as having worked on current SDR instruments; her contributions provide a computing and software-engineering foundation. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Grote Reber

Grote Reber (1911–2002) enters the discussion on the strength of a recorded career as an American electrical engineer and radio astronomer; early purpose-built radio telescope. This context is materially connected to low-noise reception, antenna sensitivity, sky-source mapping and repeatability after failed experiments.

Reber designed and repeatedly modified antennas and receivers in the demanding early practice of radio astronomy. His sensitivity experiments invite particular attention to the difference between a plausible source and a measurement chain actually capable of revealing it. A planned peer challenge might ask what happens to the apparent sky signal when antenna pattern, receiver gain, noise temperature or environmental interference changes. The engineering lesson is that negative results depend on the tested instrument and its geometry. An elegant plot by itself cannot prove

Copyright 2026, James M. Atkinson

that a faint phenomenon was absent when the instrument was not adequately sensitive.

Question 063 is the most direct illustrative assignment, asking: What is missing when an antenna is calibrated exclusively under far-field conditions? Its recommended measurement challenge is to compare antenna factor in a controlled far-field arrangement with the same antenna placed close to a conductive reference enclosure. The author must recognise the counterexample: a laboratory antenna factor may not describe the sensor's response inside an equipment rack.

Any proposed attribution must survive the challenge that a laboratory antenna factor may not describe the sensor's response inside an equipment rack. The chosen scholarly intervention has value only insofar as low-noise reception, antenna sensitivity, sky-source mapping and repeatability after failed experiments supplies a relevant explanation.

Limits of attribution: His relevance concerns receiver sensitivity and controlled weak-signal surveys; personal device identification is beyond his historical work. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Harold Hotelling

Harold Hotelling (1895–1973) was an American mathematical statistician and economist whose research helped establish multivariate statistical methods. He worked at Stanford and Columbia before founding a major statistical research programme at the University of North Carolina at Chapel Hill. His contributions included work connected with principal components

Copyright 2026, James M. Atkinson

and multivariate tests, as well as mathematical economics. These methods are relevant whenever an investigator attempts to interpret several correlated measurements as though each were a separate and independent reason for believing one hypothesis.

For example, a receiver may record amplitude, phase, bandwidth, spectral shape and repeated time-frequency features from the same candidate event. Those measurements are informative, but their joint variability matters. If they are correlated through a common source, clock, automatic-gain process or digital transformation, combining marginal confidence statements can badly overstate the strength of evidence. Hotelling's mathematical legacy provides a way to ask what the covariance structure is, whether dimensional reduction discards a discriminating feature, and whether an apparent outlier remains unusual after legitimate correlations have been accounted for. It also draws attention to the number of observations available for estimating the covariance itself.

In this constructed roundtable Hotelling acts as a statistical reviewer of correlated measurements, rather than a developer of present-day waveform classifiers. His historical work supports caution about multivariate inference; it does not verify a particular machine-learning model or signal catalogue. A responsible report should state the variables chosen, the sample from which their relationships were estimated, the stability of that sample, and the effect of alternative processing choices. His perspective is especially valuable when a visually distinctive spectral signature is presented as unique device identification without adequate population evidence.

Historical reference consulted: https://www.nationalacademies.org/read/11522/chapter/13

Copyright 2026, James M. Atkinson

Harold Stephen Black

Harold Stephen Black was an American engineer whose name is associated with the invention and practical development of negative-feedback amplification. Born in Leominster, Massachusetts, in April 1898, he completed engineering studies at Worcester Polytechnic Institute and joined the research environment which became Bell Telephone Laboratories. His work on controlling distortion in long-distance communication provided an important link between the behaviour of electronic circuits and more general principles of feedback and stability. The National Inventors Hall of Fame records his contributions, the negative-feedback amplifier patent and his subsequent professional work. The present dialogue is original educational reconstruction; it does not attribute practical familiarity with software-defined radio, modern ADC arrays or digital correlation software to Black. [B1]

Black's assigned role is to return abstract signal detection to the physical behaviour of the receiver. A mathematical algorithm may perfectly compute a matched-filter output while a local oscillator, gain-control transition or switching path generates the pulse to which it responds. Such receiver artefacts can be highly repeatable. Their existence must be tested through independent physical observations and a calibrated signal path, rather than inferred solely from a peak's position on a display. The constructed discussion invokes Black's documented engineering tradition of controlled feedback and measurement to examine these possibilities. It emphasises that a fixed template and an adaptive receiver can form a feedback-like selection mechanism, particularly when the template is learned from the same archived recording. This is a contemporary application of a historical

Copyright 2026, James M. Atkinson

intellectual method, not a claim that Black conducted any of the imaginary experiments described in the roundtable.

Harry Nyquist

Harry Nyquist was born in Nilsby, Sweden, and moved to the United States in 1907. He studied electrical engineering at the University of North Dakota and received a doctorate from Yale University in 1917. His subsequent communications research addressed transmission, thermal noise, and feedback. The engineering-history record identifies his work in the development and research organisation of the American Telephone and Telegraph Company and later at Bell Telephone Laboratories, from which he retired in 1954. It records his death in 1976. His doctorate supports the form Dr Nyquist used in this constructed discussion. [B02]

His assigned role is to examine what an acquisition preserves, rather than to treat every numerical output as a transparent view of an external signal. The connection to his documented research is substantive: transmission restrictions, sampling relationships, and feedback all require an explicit model of the system under examination. The modern discussion applies that discipline to admitted analogue bands, sample continuity, frequency mappings, and the history of digital transformations. Those particular applications are the author's present synthesis, not reconstructed statements from Nyquist's lifetime.

The biography also sets an important boundary. A foundational contribution to communications theory does not supply an experimental certificate for a present receiver. The dialogue therefore distinguishes a mathematical representation from a measured demonstration that its

Copyright 2026, James M. Atkinson

assumptions hold. Nyquist's exchanges ask how alternative inputs can become indistinguishable and how a controlled change might restore a useful distinction. They do not promise that a nominal sampling specification resolves every ambiguity. This makes his contribution complementary to Weston's physical comparison and Shannon's account of retained information. Historical standing supplies a reason for the perspective, while the receiver model and evidence must still support each modern conclusion.

Heinrich Rudolf Hertz

Heinrich Rudolf Hertz (1857–1894) enters the discussion on the strength of a recorded career as a German physicist; experimental demonstration of electromagnetic waves. This context is materially connected to propagation, resonance, electromagnetic coupling and controlled confirmation of rf phenomena.

Hertz’s experimental investigation of electromagnetic waves links theory to resonant circuits, detection methods and controlled radiation phenomena. The questions about coupling and instrument response benefit from this emphasis upon demonstrable physical change. A reconstructed intervention might insist that a suspected radiated component respond predictably to changes of geometry, polarisation or source excitation while alternative internal artefacts behave differently. The appropriate connection is resonance, propagation and the logic of laboratory tests. He must not be presented as having used modern spectrum analysers or assessed a software-defined receiver.

Question 062 is the most direct illustrative assignment, asking: Which near-field observations distinguish electric coupling from magnetic coupling

Copyright 2026, James M. Atkinson

in an enclosure? Its recommended measurement challenge is to map the same controlled component with calibrated miniature E-field and H-field probes, varying orientation and standoff. The author must recognise the counterexample: a near-field maximum cannot be interpreted as far-field radiated power without a field model.

Any proposed attribution must survive the challenge that a near-field maximum cannot be interpreted as far-field radiated power without a field model. The chosen scholarly intervention has value only insofar as propagation, resonance, electromagnetic coupling and controlled confirmation of rf phenomena supplies a relevant explanation.

Limits of attribution: He is an apt historical physical experimentalist, not an author of digital signal processing or software-defined receiver techniques. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Hendrik Antoon Lorentz

1853–1928. Dutch theoretical physicist; Nobel laureate in physics, 1902. Hendrik Antoon Lorentz was a major figure in theoretical physics whose work on electromagnetism, electrons and the relation between fields and matter influenced the development of modern physics. He pursued much of his career in the Netherlands and shared the 1902 Nobel Prize in Physics with Pieter Zeeman for research on the influence of magnetism upon radiation phenomena. His analytical contributions helped make electromagnetic descriptions more exact and provided a language for subtle distinctions between an observed field and its underlying physical causes. In

Copyright 2026, James M. Atkinson

the present fictional dialogue Lorentz challenges the sufficiency of internal phase calibration when an antenna array is used in a site with reflections, coupling and uncertain propagation. The example is modern and constructed. No claim is made that Lorentz participated in radio-forensic surveys or prescribed present-day calibration procedures. His attributed question instead extends the general virtue of precise physical modelling to an operational problem: an electronic reference may validate one part of a measuring chain without validating its antenna, installation or environment. He therefore stands for a distinction essential to trustworthy metrology, namely that a correction demonstrated at one boundary cannot simply be transported to another boundary unless the relationships between them have themselves been examined. In this educational setting the central question concerns transferability of a calibration claim. A mathematical relation may be well verified within an electronic loop and poorly tested in its external environment. The constructed exchange asks the examiner to mark the boundary where measured evidence ends and a physically plausible but still unverified model begins.

Hendrik Wade Bode

Hendrik Wade Bode was born in Madison, Wisconsin, in 1905 and died in 1982. The American Automatic Control Council reproduces an engineering-academy memorial account documenting his mathematical education, his doctorate in physics from Columbia University in 1935, and his work on electrical networks, filters, feedback, and systems engineering. After his industrial research career, he held a systems-engineering professorship at Harvard. His 1945 book on network analysis and feedback-amplifier design

Copyright 2026, James M. Atkinson

is identified in that account. The form Dr Bode is supported by the documented doctorate. [B08]

Bode's assigned peer role addresses memory and changing state in the analogue path. Correctly sampled data can faithfully describe the output of a system whose transfer during an event differs from its settled calibration response. The modern example involves a burst following a strong disturbance and an automatic gain transition. It is an original receiver case for this volume, not a claim that Bode examined the particular instrument or implementation. His established network and feedback expertise explains why this challenge follows Nyquist's account of the sampling boundary.

The question is intentionally diagnostic rather than merely cautionary. It asks whether an apparent discrepancy belongs to sampling, an inadequate analogue model, or the combined inference from them. It also asks what preceding history and state information must survive in the record. This framing prevents a well-documented digital stage from being used to certify an unobserved upstream condition. At the same time, it avoids treating every changing response as irrecoverable. A properly identified and tested model may support a restricted correction. Bode's contribution therefore helps the reader distinguish known dynamics, unsupported steady-state extrapolation, and genuine non-uniqueness in reconstructing the physical input.

Historical expertise and source concordance: Electrical network theory, feedback stability, magnitude/phase representation; not a witness to modern SDR investigations. His network arguments in Q013, Q014, Q017–020, Q022 and Q023 are historically consonant when restricted to transfer functions and control behaviour. Independent historical source: https://ethw.org/Hendrik_W._Bode

Copyright 2026, James M. Atkinson

Herbert Kroemer

Herbert Kroemer (1928–2024) was a German-born physicist; semiconductor heterostructures and high-speed electronic devices. The contribution relevant to this manuscript is analogue front-end limits, semiconductor nonlinearity, transistor behaviour and plausible trajectories of device technology.

Kroemer's theoretical and experimental work on semiconductor heterostructures provides a physical constraint on extravagant projections of electronic receiver capability. Bandwidth, nonlinearity, gain, noise and power dissipation are linked to device structures and their operating conditions, not merely to the number of bits declared by an output register. A useful debate would ask what changes when a high-speed front end becomes hotter, faces a strong blocker or moves outside its specified linear region. This work supports disciplined forecasting of devices; it does not license numerical predictions for an untested future architecture.

In the planned Question 066, the concrete issue is: How do clock feedthrough and oscillator harmonics traverse an instrument enclosure? An appropriate proposed experiment is to vary clock frequency with the RF input terminated and trace spur trajectories through shield, supply and reference changes. The corresponding interpretive caution is that a discrete line that moves with digital sampling clock settings is not necessarily an external transmission.

This contributor will be evaluated against the concrete distinction between study grounding, leakage paths, pcb return currents, shielding apertures and cross-coupling between adc clock and analogue front end. and a discrete line that moves with digital sampling clock settings is not

Copyright 2026, James M. Atkinson

necessarily an external transmission. rather than against an invented claim of personal experience with the specified apparatus.

Limits of attribution: His device-physics expertise supports physical constraints on future conversion systems, but not predictions of specific products. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Irving S. Reed

Irving S. Reed (1923–2012) was an American electrical engineer and information theorist; detection and error-correcting codes. The contribution relevant to this manuscript is coding structure, radar data detection, recoverable information and the limitations of code-family inference.

Reed contributed to coding theory and to automatic processing of radar data. In an unknown-waveform investigation, redundancy can disclose the existence of structured transmission without yielding a private payload or a unique device identity. He is an appropriate principal speaker for tests comparing syndrome consistency, synchronisation failure, channel errors and the possibility that a non-communication periodic process mimics a coded sequence. The moderator should distinguish recognising an error-control architecture from claiming successful decoding and should require controlled counterexamples. The presence of a recognised code family remains a class characteristic rather than individual identification.

In the planned Question 081, the concrete issue is: What may coding structure reveal about a waveform without decoding protected communication content? An appropriate proposed experiment is to transmit

Copyright 2026, James M. Atkinson

public test sequences using contrasting block and convolutional encoders and compare blind syndrome or correlation statistics. The corresponding interpretive caution is that a recognised code family is shared by many devices and cannot by itself identify the transmitter.

This contributor will be evaluated against the concrete distinction between consider redundancy, symbol timing, frame boundaries, error signatures and the gap between a coding-family hypothesis and a decoded message. and a recognised code family is shared by many devices and cannot by itself identify the transmitter. rather than against an invented claim of personal experience with the specified apparatus.

Limits of attribution: Coding expertise can support waveform-family analysis without implying that Reed examined any contemporary confidential traffic. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Isidor Isaac Rabi

Among the historical authorities newly considered for Volume 11 is Isidor Isaac Rabi (1898–1988). The documented career is that of a Physicist; molecular-beam magnetic resonance and the 1944 Nobel Prize in Physics. Its appropriate scope here is controlled resonance experiments, frequency selectivity, systematic perturbation and measurement calibration.

The decisive feature of his molecular-beam work was a controllable resonance experiment in which the response changed with an applied field of definite frequency. That approach is directly pertinent to experimental challenge: the investigator should manipulate one physical cause and

Copyright 2026, James M. Atkinson

observe a predicted change, rather than merely admire a stable spectral line. A reconstructed contribution may examine how resonance linewidth, field stability and measurement selectivity interact, or how a calibration source can expose instrumental responses. It must not convert Rabi into a posthumous commentator on digital protocols.

The contribution can be tested against Question 052: How should traceability of frequency standards govern coherent captures separated in time? There, the proposed discriminating experiment would compare two independently disciplined frequency chains by logging phase difference against averaging time, reference changes and loss-of-lock events. The stated failure mode is equally important: nominally identical ten-megahertz references do not imply coherent samples after an unobserved cycle slip.

For editorial quality, the speaker assignment must remain anchored in controlled resonance experiments, frequency selectivity, systematic perturbation and measurement calibration; the manuscript should plainly separate documented historical discovery from the modern test concerning separate accuracy of a frequency standard from its short-term phase stability and from the transfer path delivering that standard to adcs and mixers.

Limits of attribution: His experimental methods illuminate frequency references and the identification of instrumental artefacts, not modern time-tag metadata systems. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Copyright 2026, James M. Atkinson

Jacob Ziv

Jacob Ziv (1931–2023) enters the discussion on the strength of a recorded career as an Israeli engineer and information theorist; universal data compression with Abraham Lempel. This context is materially connected to compression, entropy, source redundancy and limits of identifying payload semantics from statistics.

Universal compression shows that apparent randomness can arise from highly structured source material after efficient encoding. This is of immediate relevance when a spectrum-monitoring examiner encounters a high-entropy burst and is tempted to infer encryption or covert activity. A credible reconstruction would distinguish entropy estimation, sample size, compressor state and the effects of framing and modulation. The comparison should include known data compressed by different methods and genuinely random test data, exposing where common tests fail. Ziv's historic work justifies a methodological warning against conflating data compressibility with a particular transmitter or user.

Question 082 is the most direct illustrative assignment, asking: When does payload compression defeat entropy-based sender attribution? Its recommended measurement challenge is to compare identical source messages before and after lossless compression and randomisation while retaining controlled framing metadata. The author must recognise the counterexample: high apparent entropy does not prove a signal is encrypted or malicious.

Any proposed attribution must survive the challenge that high apparent entropy does not prove a signal is encrypted or malicious. The chosen scholarly intervention has value only insofar as compression, entropy,

Copyright 2026, James M. Atkinson

source redundancy and limits of identifying payload semantics from statistics supplies a relevant explanation.

Limits of attribution: He can analyse compression and information content, but not assert the identity or intention of an unknown transmitter. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

James Clerk Maxwell

Among the historical authorities newly considered for Volume 11 is James Clerk Maxwell (1831–1879). The documented career is that of a Scottish mathematical physicist; classical electromagnetic field theory. Its appropriate scope here is field boundaries, propagation, polarisation and the distinction between source currents and observed electromagnetic fields.

Maxwell established the mathematical relations between electric and magnetic fields and helped show that electromagnetic radiation follows from them. His theory sets limits on casual extrapolation from a local near-field probe reading to a far-field transmitter claim. A proper exchange would distinguish source currents, boundary conditions, polarisation and the relative contribution of reactive and propagating fields. The precise conditions matter because a local maximum beside a conductor is not necessarily a remote-emitter bearing. He is an appropriate foundational physicist for the interpretation, though not a participant in present-day antenna certification procedures.

Copyright 2026, James M. Atkinson

The contribution can be tested against Question 063: What is missing when an antenna is calibrated exclusively under far-field conditions? There, the proposed discriminating experiment would compare antenna factor in a controlled far-field arrangement with the same antenna placed close to a conductive reference enclosure. The stated failure mode is equally important: a laboratory antenna factor may not describe the sensor's response inside an equipment rack.

For editorial quality, the speaker assignment must remain anchored in field boundaries, propagation, polarisation and the distinction between source currents and observed electromagnetic fields; the manuscript should plainly separate documented historical discovery from the modern test concerning distinguish far-field gain and polarisation patterns from reactive loading, cable interaction and enclosure-coupled perturbations.

Limits of attribution: His mathematical field theory can guide RF interpretation without implying a historical contribution to contemporary antenna test standards. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Jean-Baptiste Joseph Fourier

Jean-Baptiste Joseph Fourier was a French mathematician and physicist whose work on heat conduction and the analysis of functions by trigonometric series profoundly influenced later mathematical physics. Fourier's treatise on the analytical theory of heat is a major landmark in the development of methods that are now indispensable to signal processing. His historical setting preceded radio broadcasting, electronic receivers and

Copyright 2026, James M. Atkinson

digital sampling; the present text therefore uses his mathematical ideas in an explicitly fictional contemporary dialogue. It would be historically false to treat these constructed remarks as personal observations about software-defined radios, FFT implementations or digital forensic records. [T3, T7]

Fourier's relevance to the discussion rests on the separation of a mathematical representation from the physical uniqueness of its cause. A transform may rearrange the information contained in a finite list of measured values without establishing that those values uniquely determined the original analogue input. The difference bears directly on the evidential meaning of transient spectra. Finite-window multiplication, loss of phase in power displays, digital decimation and record selection can affect which physical alternatives remain observable. Modern inverse problems also require calibrated transfer functions and independent physical tests, matters that should not be conflated with the historical derivation of Fourier methods. In this roundtable, his imaginary contribution provides a disciplined mathematical perspective on the distinction between computing a spectrum correctly and identifying an electromagnetic emitter from it.

Biographical scholarship records his work amid the tumult of revolutionary and Napoleonic France, his involvement in teaching and public administration, and his later position in the Académie des Sciences. Those circumstances place his achievements in their proper historical setting rather than allowing a modern author to transport his scientific career uncritically into the digital age. The historical record also documents his analyses of heat conduction and his interactions with the scientific institutions of Paris. These are the grounds for invoking his intellectual

Copyright 2026, James M. Atkinson

tradition, not evidence of opinions on present-day investigative instrumentation.

Jerzy Neyman

Jerzy Neyman was a Polish-born statistician whose career bridged European and American mathematical research. Born in 1894 and educated in eastern Europe, he worked in Poland and in the British statistical research environment before moving to the University of California, Berkeley, in 1938. At Berkeley he helped establish a major programme of mathematical statistics, and the university records his foundational role in creating its Department of Statistics. Neyman's work on hypothesis testing, confidence intervals and sampling design contributed profoundly to twentieth-century statistical methodology. The National Academies' biographical record describes his approach as deriving procedures for carefully stated mathematical questions. None of these historical sources records him discussing present-day software-defined surveillance receivers. [B3]

His relevance here is the distinction between a procedure's repeated-use performance and the interpretation of a selected observation. A receiver may announce thousands of candidate alarms from overlapping FFT windows, but the confidence assigned to a test depends upon the experiment, the statistical population and the dependence of the decisions. Neyman's framework offers a way to articulate those premises before making an evidential claim. It also exposes the problem of choosing thresholds or clustering gaps after seeing the examples upon which the method's success is judged. Such selection may be legitimate in exploratory analysis but changes the meaning of a nominal confidence or false-positive calculation.

Copyright 2026, James M. Atkinson

In this newly constructed dialogue, Neyman insists that known injected physical events, rather than repeated frames from the same event, form the correct denominator for a declared event-level sensitivity claim. He further distinguishes the family-wise chance of at least one false alarm from the conditional probability of a signal being present when a particular detector alarm occurs. Those are different mathematical questions with different evidence requirements. His role is to sharpen the logic of inference, not to offer a historical endorsement of any particular SDR platform. The result is a considered bridge between foundational statistical scholarship and the practical ethics of forensic reporting, where visible uncertainty is preferable to unsupported certainty dressed in decimal places.

Historical expertise and source concordance: Confidence procedures, hypothesis testing and sampling design, including his historical work at University College London and Berkeley. The fictional statistical objections are methodological extrapolations, not transcripts or real modern findings. Independent historical source: https://statistics.berkeley.edu/about/history

John Bardeen

John Bardeen (1908–1991) was an American physicist whose work joined fundamental solid-state theory to practical electronics. At Bell Telephone Laboratories he participated with Walter Brattain and William Shockley in the research leading to the transistor, for which they shared the 1956 Nobel Prize in Physics. Later, at the University of Illinois, Bardeen worked with Leon Cooper and John Robert Schrieffer on the microscopic theory of superconductivity, leading to a second Nobel Prize in 1972. These are distinct accomplishments, but both exemplify his attention to the physical behaviour of materials that electronic circuits rely upon.

In a receiver, a semiconductor device is not a perfect linear amplifier. Its behaviour depends upon bias, temperature, signal amplitude, frequency

Copyright 2026, James M. Atkinson

and loading, and it may generate distortion or recover slowly following overload. Bardeen's historical expertise therefore supplies a defensible reason to challenge simplistic models of the analogue signal path. If an unexpected line appears in sampled data, the examination cannot stop at a digital spectrum estimate. It must also consider whether active devices, protective junctions or stages driven beyond their intended region could have produced a mixing product. This application of semiconductor physics must be tested with the actual device and configuration; its mere plausibility does not prove the mechanism.

The fictional peer contribution uses Bardeen as a specialist in material and device physics, not as a forensic witness to contemporary SDR surveys. His life and work do not authorise claims about proprietary receiver designs or unseen environmental transmitters. Instead his inclusion illustrates how a sound digital calculation can coexist with an incorrect physical interpretation if the analogue source of the sample stream is not independently examined. The engineering conclusion remains bounded by observed device behaviour and documented instrumentation conditions.

Historical reference consulted: https://ece.illinois.edu/about/history/hall-of-fame/bardeen

John Daniel Kraus

1910–2004. American electrical engineer, antenna specialist and radio astronomer. John Daniel Kraus became internationally recognised for his contributions to antenna engineering and radio astronomy. Trained at the University of Michigan, he worked on electromagnetic and radar-related problems during the Second World War before joining Ohio State University, where he taught, researched and helped establish a major radio observatory. His engineering achievements included important antenna

Copyright 2026, James M. Atkinson

designs and widely used writing on antennas and radio astronomy. He directed the development of large radio receiving instruments and encouraged hands-on experimentation that made the dependence of performance upon physical geometry particularly evident. In the constructed dialogue Kraus questions a familiar procurement and forensic habit: quoting one nominal direction-finding accuracy across a wide span of frequency, signal strength, installation and dwell conditions. The electronic size of the array changes with wavelength; so do coupling, sensitivity and ambiguities. The modern validation requirements described in the answer are original editorial synthesis, not statements taken from Kraus's books. His contribution is chosen to remind the reader that even a refined algorithm remains coupled to an antenna's physical aperture, pattern, installation and interaction with the surrounding environment. The accuracy warranted by a field result must be demonstrated over the actual conditions rather than borrowed from a convenient summary figure. His research and teaching show that the antenna is not a detachable ornament on a receiving instrument. It establishes the interface between the measurable field and the connected electronics. The dialogue uses this principle to insist that installation, frequency and burst duration be reflected in the reported performance, rather than buried under a single instrument specification.

John Harrison

The historical record identifies John Harrison (1693–1776) with chronometer error, environmental disturbance, calibration and the principle of traceable time. An accurate professional description is an English clockmaker and inventor; marine chronometers and precision timekeeping.

Copyright 2026, James M. Atkinson

Harrison's chronometers transformed maritime navigation by confronting the difficulty of accurate timekeeping under changing physical conditions. His relevance to a modern frequency-standard debate is historical and metrological, rather than digital. A careful analogy would examine environmental influence, repeatability, mechanical disturbance and the need for a tested reference independent of the observer's wish for precision. Chronometer error at sea demonstrates why a clock's nominal design is not sufficient evidence of its behaviour in use. The moderator must refrain from attributing knowledge of atomic clocks, RF distribution amplifiers or network timing to Harrison.

Within the new programme, Question 052 provides a suitable test of this expertise: How should traceability of frequency standards govern coherent captures separated in time? The test design calls for the investigator to compare two independently disciplined frequency chains by logging phase difference against averaging time, reference changes and loss-of-lock events. The possible error is straightforward: nominally identical ten-megahertz references do not imply coherent samples after an unobserved cycle slip.

The intended teaching purpose is to illuminate separate accuracy of a frequency standard from its short-term phase stability and from the transfer path delivering that standard to adcs and mixers. without blurring the quite different historical evidence concerning chronometer error, environmental disturbance, calibration and the principle of traceable time.

Limits of attribution: Harrison contributes historical mechanical timing expertise only; no digital, RF or network clock procedures are attributed to him. This is a modern scholarly introduction, not a transcription of historical

Copyright 2026, James M. Atkinson

speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

John Robinson Pierce

John Robinson Pierce (1910–2002) was an American electrical engineer and communication scientist whose long career at Bell Telephone Laboratories included work on travelling-wave tubes and the early development of communications satellites. The California Institute of Technology preserves an oral-history record of his Bell Labs research, radar-related work and involvement in the Echo and Telstar satellite programmes. He later returned to academic research and also took an interest in psychoacoustics and computer-generated sound. His work exemplified the interaction of propagation physics, electronic apparatus and system-level communication design.

Pierce's appropriate contribution to the roundtable is to ask whether a receiver observation is being interpreted within a sufficiently complete communication system. A spectral line or transient pulse must be considered in relation to the source, path, antenna, receiver and detector, rather than assigned to a transmitter merely because it appears in a saved image. At microwave frequencies, components and transmission paths can impose strong frequency selectivity and phase variation. The result may be especially misleading when comparing observations from geographically separated sensors or when trying to infer a source's behaviour from one limited capture window.

An imagined Pierce intervention should not claim that he tested modern SDR forensic software. His documented background supports questions

Copyright 2026, James M. Atkinson

about communication channels, amplification, propagation and instrumentation integration. The modern survey must supply measurements of its own receiver noise, timing and front-end transfer function. The principal lesson is methodological as well as technological: communication engineering requires a complete system model, and forensic attribution requires evidence distinguishing that model from plausible alternatives. A theory of a possible path is useful only where the record can test whether that path was actually operating.

Historical reference consulted:
https://digital.archives.caltech.edu/collections/OralHistories/OH_Pierce_J/

John von Neumann

John von Neumann (1903–1957) was a Hungarian-born American mathematician whose research reached across mathematical foundations, quantum theory, game theory, numerical computation and the architecture of electronic computing systems. He participated in major wartime and post-war scientific programmes and made fundamental contributions to the understanding of computation as a physical and mathematical process. Although his name is attached to influential computer-architecture concepts, the historical attribution of specific stored-program developments is more complex than a single-inventor story. His lifetime ended before the modern software-defined radio emerged.

Within this roundtable, von Neumann's work is useful for distinguishing numerical operations from the information present in their inputs. A computer may implement a mathematically correct transform while the samples supplied to it are clipped, aliased or badly timed. Similarly, a reconstruction algorithm can produce a definite array of values even where

Copyright 2026, James M. Atkinson

multiple physical waveforms were compatible with the retained record. Numerical stability, finite precision and the form of the computational model must therefore be examined separately from the validity of the analogue acquisition. Where a complex signal is transformed or decimated, the researcher should state which degrees of freedom remain available for later analysis.

His fictional peer challenge appropriately addresses mathematical computation, modelling and the epistemic limits of algorithms. It must not imply firsthand knowledge of present receiver firmware, and it should not use his stature to resolve an engineering dispute for which no contemporary measurement has been supplied. The historical connection is strongest where mathematical formalisation clarifies the experiment: describe the input, the computational operation, the physical assumptions and the observable consequence of each alternative model. That is a properly bounded use of his research legacy.

Historical reference consulted: https://mathshistory.st-andrews.ac.uk/Biographies/Von_Neumann/

John Wilder Tukey

John Wilder Tukey was an American mathematician and statistician closely associated with Princeton University and Bell Telephone Laboratories. Historical accounts document his education at Brown and Princeton, influential contributions to exploratory data analysis, and his collaboration with James W. Cooley on the fast Fourier transform algorithm. His career extended across mathematical statistics, numerical computing and practical applications in science and engineering. He received significant professional honours, including the United States National Medal of Science. The breadth of his work makes him a particularly appropriate intellectual

Copyright 2026, James M. Atkinson

figure for an imagined debate about what analysts learn from data before they possess a settled model. [R6]

The present dialogue does not reproduce Tukey's historical utterances. It uses his documented methodological concerns as a basis for new discussion of robust spectral summaries and event selection. A robust measure of ordinary background can be statistically useful while suppressing an intermittent transmission whose unusual appearance is precisely why a defensive investigator wishes to preserve it. Exploratory detection may reveal patterns that motivate new hypotheses, but confirmatory performance must be evaluated with controlled trials and a disclosed selection rule. These modern forensic applications are newly authored educational constructions. They should not be mistaken for reports of Tukey personally examining software-defined surveillance receivers or prescribing the specific procedures presented in this volume.

His methodological example encourages scientists to examine the behaviour of individual observations before accepting a reassuring aggregate. Within a surveillance inquiry, that disposition is relevant to both the unexpectedly high measurement and the awkward missing interval. Neither should be erased merely to improve the apparent smoothness of a plotted background.

Historical expertise and source concordance: Exploratory data analysis, statistical practice, computing and co-development of the fast Fourier transform; source-compatible for critiques of display-selected evidence. Independent historical source: https://history.computer.org/pioneers/tukey.html

Jules Henri Poincaré

1854–1912. French mathematician, theoretical physicist and philosopher of science. Henri Poincaré pursued a remarkably wide mathematical and

Copyright 2026, James M. Atkinson

philosophical career, contributing to differential equations, celestial mechanics, mathematical physics and the foundations of later developments in topology. Born in Nancy, he studied and worked in France, where his investigations repeatedly exposed the relationship between a precise mathematical formalism and the limits of prediction in a complicated physical system. His writings also addressed the role of convention, hypothesis and scientific explanation. In the present constructed conversation, he presses Professor Bracewell to distinguish mathematical uniqueness from numerical stability and from the evidential separation of competing source hypotheses. An algorithm may return one solution despite severe ill-conditioning, an untested prior or a second physical arrangement compatible with the data. The speech does not assert that Poincaré formulated modern SDR forensic requirements. Rather, it places his methodological insistence on the careful interpretation of mathematics within a present-day inverse problem. The role is particularly relevant where a highly detailed computed coordinate seems to outrun the finite, noisy and incomplete measurements from which it was inferred. His question requires the examiner to test how the output changes when assumptions and nuisance parameters change, and to present non-unique alternatives when the observation cannot decide between them. The question is chiefly epistemological: a numerical solution can be formally correct and practically unstable, or stable within a model that excludes the true physical cause. The dialogue links this distinction to receiver localisation and to the duty to preserve alternate hypotheses. This is an application of mathematical caution, not a claimed historical quotation.

Copyright 2026, James M. Atkinson

Karl Guthe Jansky

Among the historical authorities newly considered for Volume 11 is Karl Guthe Jansky (1905–1950). The documented career is that of an American radio physicist; discovered radio emission from the Milky Way while investigating terrestrial interference. Its appropriate scope here is environmental radio noise, antenna directionality, propagation and disciplined differentiation of source origins.

Jansky was investigating sources of interference affecting transatlantic radiotelephony when he established that one persistent component of observed radio noise arrived from beyond the Earth. His observational discipline is essential for separating a genuine incident field from equipment artefacts and misleading local assumptions. An appropriate question asks how changing antenna direction, sidereal timing, weather, receiver state and reference loads alters the competing predictions. The relevance is the act of distinguishing possible origins using repeatable evidence. It does not turn a twentieth-century sky-noise investigation into an endorsement of contemporary software classification claims.

The contribution can be tested against Question 068: How can antenna substitution distinguish incident RF energy from instrument-generated signals? There, the proposed discriminating experiment would run antenna, matched-load, dummy-source and second-front-end substitutions under constant receiver state. The stated failure mode is equally important: a disappearing feature after antenna removal can also arise from changes in gain-control or impedance environment.

For editorial quality, the speaker assignment must remain anchored in environmental radio noise, antenna directionality, propagation and

Copyright 2026, James M. Atkinson

disciplined differentiation of source origins; the manuscript should plainly separate documented historical discovery from the modern test concerning use known source impedance, preselector bypass, shielded terminations and independent input paths to establish where energy entered the measurement chain.

Limits of attribution: He contributes directly to source discrimination and radio background studies, not digital modulation classifications invented decades later. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Karl Pearson

Karl Pearson (1857–1936) was a British mathematician and statistician associated particularly with University College London and the institutional development of mathematical statistics. He worked on the formal treatment of correlation, distributions and quantitative comparison, and helped establish the journal Biometrika. His intellectual and professional career also included eugenics research and advocacy. That history is an important qualification, not an achievement to be imported uncritically into modern forensic practice; his contributions to mathematical method can be studied without accepting the social claims to which he sometimes applied them.

Pearson's statistical methods enter receiver engineering when investigators compare measurement groups, estimate relationships among variables or assert that a spectral anomaly is exceptional. Correlation between successive samples or between frequency bins does not establish physical causation. An elevated correlation coefficient can be generated by a

Copyright 2026, James M. Atkinson

shared gain-control response, common oscillator drift or a signal-processing choice rather than by two independent sources. A statistical model must distinguish the quantity estimated from the mechanism inferred, particularly where a threshold or feature set has been selected after examining the same data. These concerns are directly relevant to laboratory challenge tests and the analysis of large spectral catalogues.

The constructed contribution attributed to Pearson is limited to statistical reasoning and its interpretive conditions. It does not give his views special authority in contemporary law, sociology or ethics, and does not suggest he could evaluate later software-defined instruments. A defensible use of his methods will name the sample, explain dependence, show the consequences of alternatives and avoid treating statistical association as unique source identification. His biography makes the distinction between mathematical accomplishment and broader historical judgement explicit.

Historical reference consulted: https://catalogues.royalsociety.org/CalmView/Record.aspx?id=NA8002&src=CalmView.Persons

Lord Rayleigh

1842–1919. British physicist and Nobel laureate in physics, 1904. John William Strutt, third Baron Rayleigh, made foundational contributions to acoustics, optics, waves and experimental physics. His work on wave phenomena and diffraction helped establish enduring methods for thinking about resolution and the limitations of finite apertures. He occupied important scientific positions in Britain, including service at Cambridge and leadership of the Royal Society, and received the 1904 Nobel Prize in Physics for work associated with the density of gases and the discovery of argon. The present contribution borrows the discipline of careful discrimination,

Copyright 2026, James M. Atkinson

not a quotation or purported historical research on modern arrays. A direction-finding processor can draw a sharply located maximum without demonstrating that two nearby emitters are resolvable or that environmental bias is absent. Resolution, precision and accuracy therefore have separate evidential meanings. Rayleigh's assigned question asks an investigator to demonstrate those differences rather than to count pixels or decimal places in a finished display. The historical authority of his investigations must not be used to suggest endorsement of a particular modern algorithm, receiver or forensic threshold. His function in this deliberately constructed conversation is to make the physical aperture and the population of competing wavefronts visible behind the apparently effortless output of an electronic processor. Rayleigh appears not as a modern compliance authority but as an exemplar of patient experimental distinction. His assigned question encourages separate study of resolution, bias and random variation. In scholarly terms, each quantity answers a different question, and none becomes a fact merely because software can display several decimal places.

Lotfi Asker Zadeh

Lotfi Asker Zadeh (1921–2017) was an electrical engineer and computer scientist whose work extended from system theory to artificial intelligence and fuzzy-set methods. After education including the University of Tehran, the Massachusetts Institute of Technology and Columbia University, he joined the faculty of the University of California, Berkeley. His research in time-varying systems, sampled-data analysis and state-space representations preceded his influential 1965 paper introducing fuzzy sets. Berkeley's institutional account provides a useful chronology connecting

Copyright 2026, James M. Atkinson

these stages of his work rather than reducing his career to the single adjective 'fuzzy'.

His relevance to receiver analysis arises when an investigator must distinguish uncertainty in a physical measurement from vagueness in the categories used to describe it. A poorly resolved burst may be partially compatible with several signal classes, and software may assign degrees of membership to those classes. Such a classification can be useful for triage but is not automatically a calibrated probability that a particular transmitter was present. Further, a system-state model must account for changing filter, gain and timing states if it is to support retrospective interpretation. These questions belong naturally to Zadeh's documented interests in systems, mathematical representations and approximate reasoning.

The hypothetical contribution should therefore challenge analysts who equate a confidence-like score with a forensic posterior probability without validating that interpretation. It should also ask whether a flexible classifier preserves a stable definition across hardware and software revisions. Zadeh did not personally test the contemporary SDR systems described in the volume; his historical work is an intellectual resource for handling incomplete classification and dynamic system models. Physical source attribution still requires independent RF observations, calibration and a properly specified inferential procedure.

Louis Essen

Louis Essen (1908–1997) enters the discussion on the strength of a recorded career as a British physicist and metrologist; precision frequency

Copyright 2026, James M. Atkinson

measurement and the caesium atomic clock. This context is materially connected to frequency standards, clock comparisons, long-term drift and the practical problem of traceability.

His metrological career connected accurate oscillator behaviour to comparisons of standards under practical laboratory conditions. The planned clock questions require the distinction between frequency offset, short-term fluctuation, environmental drift and the uncertainty of transfer between devices. An appropriate discussion could compare a reference counter with two independently operated oscillators, testing whether an apparent improvement after averaging reflects genuine reference stability or merely cancellation of common errors. It should record temperature, control state, holdover and frequency history, so that the authority of a standard is not inferred from its label.

Question 053 is the most direct illustrative assignment, asking: When can oscillator disciplining conceal rather than correct a phase discontinuity? Its recommended measurement challenge is to apply controlled reference interruptions and record both raw phase residuals and closed-loop control voltages before and after reacquisition. The author must recognise the counterexample: a clean long-term Allan deviation curve can conceal a short, consequential phase step.

Any proposed attribution must survive the challenge that a clean long-term allan deviation curve can conceal a short, consequential phase step. The chosen scholarly intervention has value only insofar as frequency standards, clock comparisons, long-term drift and the practical problem of traceability supplies a relevant explanation.

Copyright 2026, James M. Atkinson

Limits of attribution: Essen may address reference accuracy and metrological discipline; detailed FPGA or software-clock behaviour is a modern editorial extension. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Marvin Lee Minsky

Among the historical authorities newly considered for Volume 11 is Marvin Lee Minsky (1927–2016). The documented career is that of an American mathematician and computer scientist; artificial intelligence research. Its appropriate scope here is algorithmic classification, machine perception, model dependence and the limits of intelligent inference.

Minsky's work helped build the intellectual foundations of artificial intelligence and machine perception. The present technical problem is not whether a classifier can produce a label, but whether the label is warranted when signals, receiver hardware and operating conditions differ from those represented in training. A reconstructed discussion might identify the difference between a pattern memorised from receiver artefacts and a feature causally associated with an external emission. It should demand held-out apparatus and environment tests. Contemporary machine-learning architectures remain an editorial context, not part of an invented historical laboratory record.

The contribution can be tested against Question 104: How should machine-assisted RF anomaly detection be assessed under distribution shift? There, the proposed discriminating experiment would reserve independent locations, receiver hardware and interference regimes as held-out challenges rather than random windows from the same recording. The

Copyright 2026, James M. Atkinson

stated failure mode is equally important: an accurate classifier on correlated test data can be unreliable when the receiver, room or emitters change.

For editorial quality, the speaker assignment must remain anchored in algorithmic classification, machine perception, model dependence and the limits of intelligent inference; the manuscript should plainly separate documented historical discovery from the modern test concerning examine training-set contamination, novelty scoring, changing gain states, open-set errors and the possibility of memorising instrument artefacts.

Limits of attribution: He provides foundational AI reasoning, not knowledge of trained RF classifiers or evaluation datasets introduced after his era. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Maurice Stevenson Bartlett

Maurice Stevenson Bartlett was a British statistician whose work connected probability theory with practical observations evolving in space and time. Born in London on 18 June 1910, he studied mathematics at Cambridge and contributed to the theory of statistical processes, multivariate analysis and spectral estimation. His election as a Fellow of the Royal Society in 1961 recognised the importance of that scientific work. The Royal Society's historical catalogue identifies his later academic position as Professor of Biomathematics at Oxford and preserves research records concerning the development of statistical models. The precise modern receiver applications in this discussion are new educational constructions rather than assertions about what Bartlett personally examined. [B1]

Copyright 2026, James M. Atkinson

Bartlett is especially pertinent to overlapping spectral analysis because averaging does not cease to be a statistical problem when a Fourier transform is involved. He was associated with periodogram and time-series methods which helped establish the distinction between individual noisy spectral estimates and procedures that combine information across a record. His intellectual legacy assists the present discussion at the level of correlation, covariance, model assumptions and the meaning of a statistical unit. A receiver can generate many periodograms, but their mean's uncertainty depends upon how they were produced and on any dependence among them. The temptation to divide an error estimate by the square root of the number of frames without examining sample reuse is precisely the kind of modelling error his methodological perspective helps expose.

In the constructed dialogue, Bartlett therefore represents the requirement to analyse correlations between overlapping outputs and to define which quantity a receiver is estimating. His role does not imply that he knew contemporary SDR software or judged the performance of any instrument marketed today. It illustrates how established statistical reasoning can interrogate an engineering method without confusing a hypothetical application with a historical quotation. His contribution also links British mathematical statistics with the practical demands of forensic evidence: an uncertainty interval has meaning only in relation to a measurement model and a repeatable experimental procedure. The educational portrayal should be read in that limited spirit.

Michael Faraday

Michael Faraday (1791–1867) was a British experimental physicist and chemist; electromagnetic induction and field reasoning. The contribution

Copyright 2026, James M. Atkinson

relevant to this manuscript is magnetic coupling, induction, conductor and shield interactions, and experiments testing the physical route of interference.

Faraday's experiments made electromagnetic induction a physical fact subject to repeatable observation. Within technical surveillance countermeasures, his work bears upon magnetic coupling between wiring, equipment enclosures and nearby sensors. A well-chosen experiment changes loop orientation, separation and current while preserving the measurement chain. Such a test may differentiate a genuine local magnetic field from a response introduced by a cable or receiving probe. Faraday's historical contribution is the experimental account of induction and fields. Modern calibrated near-field probe practices should be attributed to contemporary engineering rather than to his nineteenth-century laboratory.

In the planned Question 062, the concrete issue is: Which near-field observations distinguish electric coupling from magnetic coupling in an enclosure? An appropriate proposed experiment is to map the same controlled component with calibrated miniature E-field and H-field probes, varying orientation and standoff. The corresponding interpretive caution is that a near-field maximum cannot be interpreted as far-field radiated power without a field model.

This contributor will be evaluated against the concrete distinction between compare probe orientation, source impedance, field gradients, loop area and distance scaling below the reactive near-field boundary. and a near-field maximum cannot be interpreted as far-field radiated power without a field model. rather than against an invented claim of personal experience with the specified apparatus.

Copyright 2026, James M. Atkinson

Limits of attribution: His laboratory investigations inform near-field physics, whereas modern VNA calibration and digital RF instruments are later editorial applications. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Norbert Wiener

Norbert Wiener was an American mathematician born in 1894 and deceased in 1964. MIT Press records his long service in MIT's mathematics department, beginning in 1919, and identifies his books on cybernetics, prediction, and related mathematical subjects. The Science Museum Group's institutional biography records his doctorate and his work connecting feedback, control, and communication. These records support the form Dr Wiener. His inclusion in this volume concerns those demonstrated mathematical and systems interests, not a religious or theological role. [B12, B12a]

Wiener's constructed question examines the feedback between observer, instrument, and retained evidence. An adaptive receiver or an operator responding to preliminary results can change the conditions under which later observations are selected. Such adaptation may be legitimate and useful, yet the resulting archive cannot automatically be treated as an unselected record of the full observation period. The hypothetical triggered-retention example is newly authored for this volume. It is not represented as an experiment conducted by Wiener or as a historical prediction of a particular modern platform.

Copyright 2026, James M. Atkinson

The contribution asks how discovery can remain productive without allowing selection to disguise incomplete coverage. It therefore links control and communication concerns with the evidential distinctions developed by the other speakers. The relevant question is not whether the observer is perfectly detached, but whether the coupled procedure is defined and its consequences can be examined. A record of selected events can support some findings while leaving prevalence or non-detection claims unresolved. Wiener challenges Popper to identify an experiment capable of testing those omissions rather than merely praising openness to criticism. His role closes the peer sequence by bringing the operator and acquisition policy back inside the system boundary that the first principal respondent established.

Historical expertise and source concordance: Mathematics of stochastic processes, prediction, feedback and cybernetics. Conditional observer-and-control-loop reasoning is consistent with that body of work; modern firmware examples are editorial applications. Independent historical source: https://mitpress.mit.edu/author/norbert-wiener-18445/

Norman Foster Ramsey Jr.

Norman Foster Ramsey Jr. (1915–2011) was an American physicist; separated oscillatory fields and hydrogen maser. The contribution relevant to this manuscript is atomic and molecular resonance, clock precision, and distinction between reference frequency and phase stability.

In a receiver with several clock domains, the question of when an oscillator was stable differs from the question of whether every derived clock preserved phase. His separated-oscillatory-fields research gives a rigorous conceptual basis for asking how a frequency reference is tested against its own noise and against independent instruments. In a proposed comparison, the moderator should ask for the averaging interval, the duration of any reference interruption, the time of reacquisition and a

Copyright 2026, James M. Atkinson

measurement of the residual phase. Those details determine whether two recordings may legitimately be combined coherently.

In the planned Question 052, the concrete issue is: How should traceability of frequency standards govern coherent captures separated in time? An appropriate proposed experiment is to compare two independently disciplined frequency chains by logging phase difference against averaging time, reference changes and loss-of-lock events. The corresponding interpretive caution is that nominally identical ten-megahertz references do not imply coherent samples after an unobserved cycle slip.

This contributor will be evaluated against the concrete distinction between separate accuracy of a frequency standard from its short-term phase stability and from the transfer path delivering that standard to adcs and mixers. and nominally identical ten-megahertz references do not imply coherent samples after an unobserved cycle slip. rather than against an invented claim of personal experience with the specified apparatus.

Limits of attribution: Ramsey belongs in discussions of frequency standards, clock stability and coherent measurements. He must not be represented as a designer of contemporary SDR firmware. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Oliver Heaviside

1850–1925. British electrical engineer, mathematician and pioneer of electromagnetic theory. Oliver Heaviside was a largely self-taught mathematical physicist whose work transformed the practical and analytical

Copyright 2026, James M. Atkinson

treatment of electromagnetic theory. Born in London, he began professional life in telegraphy, where the behaviour of electrical signals along conductors motivated a lifetime of independent investigation. He recast Maxwellian electromagnetic theory into forms widely used in engineering, studied transmission lines, developed operator methods and examined effects that could limit or improve the passage of signals through real circuits. His theoretical work also contributed to the prediction of a conducting region of the upper atmosphere important to radio propagation. His career is notable because some of its most consequential ideas emerged outside the conventional institutional arrangements of British science. In the constructed roundtable he challenges the casual substitution of a bearing ray for a complicated field near conductive structures. Cable trays, enclosures and nearby metalwork can shape the observations of a survey instrument even when a remote source is unchanged. The specific SDR measurements, antenna movements and reporting duties described in the question belong to this volume, not to Heaviside's historical papers. His role is to keep the measurement anchored in boundary conditions and in the physical relationships that give a displayed direction meaning. The relevance is not simply historical admiration for equations. Conductors, insulation, impedance and the dimensions of apparatus remain actual contributors to electromagnetic measurement. By challenging the validity of a far-field bearing near metallic structures, his assigned role guards against a common error: confusing a convenient representation of a field with a demonstration of its source.

Historical expertise and source concordance: Transmission-line theory, electromagnetic field analysis and operator calculus. Relevant to cable reflections and filter transients; historically an independent researcher rather than a modern receiver-software engineer. Independent historical

source: https://www.theiet.org/membership/library-and-archives/the-iet-archives/biographies/oliver-heaviside-1850-1925

Percy Williams Bridgman

Percy Williams Bridgman was an American physicist whose career was closely associated with Harvard University. His investigations of matter under high pressure required the development of specialised experimental apparatus, and he received the Nobel Prize in Physics in 1946 for work in that field. The Society of Rheology's institutional account records his Harvard education, including his doctorate, his long teaching career, and his interest in the foundations of physical thought. It supplies the life dates 1882–1961. Professor Bridgman is the form used here. [B06]

His peer question is directed to the identity of the measured quantity. Two calibrated procedures can produce different numbers because they estimate different properties, not because one instrument is defective. Conversely, different procedures intended to estimate the same quantity require evidence of the relevant correspondence. Bridgman's documented combination of experimental apparatus and philosophical interest provides an appropriate perspective for this distinction. The burst and filtering example in the dialogue is newly authored for the receiver context and is not presented as a historical problem he personally investigated.

The editorial aim is to prevent operational detail from becoming either an empty checklist or an arbitrary definition. A procedure must be specific enough to reproduce, while the intended comparison must be clear enough to judge whether a changed procedure still answers the same question. Bridgman's contribution therefore challenges Weston rather than merely endorsing him. It asks what remains invariant across a method change and

Copyright 2026, James M. Atkinson

how the examiner would establish equivalence. Readers should not infer from the historical name that every modern claim has been validated. The exchange supplies a disciplined question; its answer must still be supported by the chosen measurement model, reference conditions, and tests of the actual receiver chain.

Historical expertise and source concordance: Experimental high-pressure physics and operational analysis of measurement. The work provides a defensible lens for physical reference planes and operational definitions, not evidence that Bridgman developed modern spectrum-surveillance procedures. Independent historical source: https://fi.edu/en/awards/laureates/percy-williams-bridgman

Peter Elias

Among the historical authorities newly considered for Volume 11 is Peter Elias (1923–2001). The documented career is that of an American information theorist and MIT professor; source and channel coding. Its appropriate scope here is redundancy, convolutional encoding, decoding assumptions and quantifying transmitted information.

Elias developed important ideas in source and channel coding, including convolutional codes and the representation of digital information. His work is useful when the physical observation suggests redundancy or a structured stream. A rigorous analysis would consider how much information about a code can be extracted from a short, corrupted or truncated capture, how erasures should be represented, and when a statistical match may be attributable to common formatting alone. It should also explain why the absence of recognised redundancy does not prove a channel was unoccupied. His contribution would remain theoretical and specific to coding.

Copyright 2026, James M. Atkinson

The contribution can be tested against Question 086: How should beacon-like repetition be described without assuming a named protocol? There, the proposed discriminating experiment would compare laboratory beacon generators with periodic industrial control bursts under matched observation gaps. The stated failure mode is equally important: identical intervals occur in many unrelated systems, especially after receiver scheduling is considered.

For editorial quality, the speaker assignment must remain anchored in redundancy, convolutional encoding, decoding assumptions and quantifying transmitted information; the manuscript should plainly separate documented historical discovery from the modern test concerning analyse timer quantisation, drift, jitter and packet-length patterns without attaching device identity to an unverified standard.

Limits of attribution: His coding work supports analytical treatment of structure; claims about named modern wireless protocols are editorial applications, not historical testimony. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

Ralph Beebe Blackman

Ralph Beebe Blackman (1904–1990) was an American mathematician and engineer whose career at Bell Telephone Laboratories combined circuit research, statistical signal analysis and practical data processing. An IEEE biographical account records his early work on acoustics, electromechanical transducers and filtering, followed by studies of electrical networks,

Copyright 2026, James M. Atkinson

equalisation and feedback. He is particularly associated with spectral-analysis methods and with the work on power-spectrum measurement published with John Wilder Tukey. The familiar Blackman window reflects his place in the history of practical frequency-domain estimation, not an implication that one window is optimal for every detection problem.

Blackman's relevance is immediate in the study of finite records. A discrete spectral estimate depends on the selected data window, its equivalent noise bandwidth, sidelobe behaviour and the way adjacent frames are averaged. A short burst can disappear in an average or spread into neighbouring frequencies under a poorly understood window; a visually narrow peak can also arise from processing choices. When a monitoring report uses a frequency-bin value as physical evidence, the investigator should disclose the window length, weighting, overlap and relation between the recorded samples and the displayed estimate. These properties affect both resolution and the effective number of independent detection opportunities.

In the editorial discussion Blackman can legitimately challenge the mathematics and practice of spectral estimation, while another contributor addresses the receiver's analogue integrity. He is not represented as having used modern interactive waterfalls or device-fingerprinting systems. His documented research supports a sharper question: which characteristics of the measurement belong to the source, and which follow from the finite-window estimator selected by the analyst? Answering it requires both the retained original samples and a transparent account of every processing choice.

Copyright 2026, James M. Atkinson

Ralph Vinton Lyon Hartley

Ralph Vinton Lyon Hartley was born in Nevada in 1888 and died in 1970. The engineering-history record describes his undergraduate education at the University of Utah and subsequent Oxford study as a Rhodes Scholar. His research included oscillator circuits, receiver development, and the relation between information transmission, bandwidth, and duration. The record also identifies his work on repeaters, carrier transmission, and later control problems. He is addressed as Mr Hartley here; professional distinction is not used to invent an academic title. [B09]

His peer question challenges the idea that a wide recorded band and a large numerical word automatically make one acquisition superior to another. The constructed example contrasts a broad but compromised observation with a narrower path that preserves the feature of interest under better-characterised conditions. Hartley's documented concern with transmission and its restrictions makes him an appropriate interlocutor. The particular converter and archive comparison is an original modern application rather than a historical statement attributed to him.

The editorial purpose is to force the comparison to retain its task. A record may provide broader context while supporting a weaker measurement of a particular component. Another may support a precise restricted observation while excluding much of the surrounding spectrum. Neither limitation should be concealed by a single advertised number. Hartley's contribution asks what alternatives the data distinguish and what assumptions permit the resulting comparison. It also leads naturally to the

Copyright 2026, James M. Atkinson

question of complementary acquisition paths, which require demonstrated timing and reference relationships before they are combined. His role is not to dismiss broad capture, but to insist that its benefit be described through the evidence it preserves for the specified inference rather than through the visual or numerical size of its output.

Richard Wesley Hamming

Richard Wesley Hamming was an American mathematician and computer scientist associated with the development of error-detecting and error-correcting codes, numerical computation and digital signal analysis. Born in Chicago in 1915, he studied mathematics at the University of Chicago, the University of Nebraska and the University of Illinois, where he completed his doctorate. His work during the Second World War included computational activity at Los Alamos; he subsequently spent a long period at Bell Telephone Laboratories, where the mathematical and engineering challenges of reliable communication and computation informed major contributions. He later taught at the Naval Postgraduate School in Monterey. His scientific name is associated with Hamming codes and a widely used spectral window. The National Academy of Engineering's memorial tribute, a mathematical biography and other historical institutional accounts record these features of his life and work. [S9]

Hamming's peer intervention here concerns the distinction between a mathematical weighting operation and a physical measurement improvement. A taper changes the response of the finite-record estimator. Coherent gain and equivalent noise bandwidth are useful descriptive quantities, but neither is a universal restoration of an arbitrary transient waveform. The question therefore draws from the genuine disciplinary

Copyright 2026, James M. Atkinson

terrain of numerical analysis, spectral windows and computational reliability, while treating the specific forensic hypothetical as newly authored educational application. Hamming did not participate in this discussion, did not evaluate the instruments described, and is not credited with the numerical examples created for the volume. His voice serves to challenge the careless conflation of visual frequency interpolation, sample acquisition, and improvements in the information actually recorded. That separation is central both to technical measurement and to the responsible presentation of expert evidence.

Ronald Newbold Bracewell

1921–2007. Australian-born radio astronomer and electrical engineer. Ronald Newbold Bracewell was born in Sydney and pursued mathematics, physics and engineering before developing an international career in radio astronomy and electrical engineering. During the Second World War he worked on microwave radar research; afterwards he undertook graduate work at Cambridge and contributed to the growing discipline of radio astronomy. He later joined the faculty of Stanford University, where his research embraced antennas, Fourier analysis, astronomical imaging, image construction and the reconstruction methods that would also influence medical imaging. His influential book on Fourier transforms became a familiar companion to advanced students of signals and systems. Bracewell's work is particularly apt for this dialogue because a reconstructed image may depend heavily on the available frequency information, sampling geometry and assumptions inserted into an inverse calculation. In this fictional educational exchange he is asked to test whether a highly detailed source map necessarily corresponds to one uniquely established physical

Copyright 2026, James M. Atkinson

cause. The technical examples involving RF sources, multipath and receiver-generated mixing products are constructed applications rather than historical quotations. They illustrate the general principle that successful inversion requires attention to what the measurement operator has retained and to what has been supplied by assumptions. His assigned role also helps distinguish honest model-based reconstruction from unsupported confidence in the visual detail of a processed result. For this volume, his biography also illustrates a connection between radio and medical imaging: both must interpret incomplete observations through physical models. Whether the output is an image or a map, apparent detail is not a substitute for identifiability. The dialogue uses that insight to demand competing explanations and empirical checks of reconstruction stability.

Rudolf Emil Kálmán

1930–2016. Hungarian-born American mathematician and systems theorist. Rudolf Emil Kálmán was born in Budapest and developed an extraordinary career at the intersection of mathematics, electrical engineering and automatic control. After study in the United States and important work in linear systems, he became closely associated with modern state-space methods, mathematical observability and the filtering technique bearing his name. The Kalman filter provided a systematic framework for updating an estimate of an unobserved state from measurements and an explicit model of dynamics and uncertainty. Its influence extends across navigation, aerospace engineering, robotics and communications. Kálmán held senior academic posts including appointments associated with the University of Florida and the Swiss Federal

Copyright 2026, James M. Atkinson

Institute of Technology in Zürich. The present dialogue uses his disciplinary contribution to illuminate a common forensic hazard: a tracking system can produce a persuasive trajectory even when sensor geometry, prior assumptions or measurement selection prevent the trajectory from being uniquely determined. The source's movement, the sensor's movement and the algorithm's adaptation must not be silently conflated. The particular SDR scenarios and speech supplied here are modern editorial constructions, not historical statements. His role is to compel the investigator to disclose the dynamical model, observation likelihood, conditions of observability and persistent influence of initial assumptions before turning a sequence of bearings into the story of a moving transmitter. A further editorial distinction is between the state that a model predicts and the variable that a sensor has actually measured. In a forensic setting the distinction carries consequences for disclosure, reproducibility and cross-examination. The assigned dialogue deliberately requires a tracking system to reveal predicted intervals, observation gaps, competing associations and assumptions about movement.

Sir David Cox

Sir David Roxbee Cox (1924–2022) was a British statistician whose work influenced experimental design, statistical inference, survival analysis and the interpretation of complex observational data. His academic career included positions at Birkbeck College, Imperial College London and the University of Oxford, where he served as Warden of Nuffield College. He also edited Biometrika for many years. His influence reaches beyond the proportional hazards model associated with his name; he was a major

Copyright 2026, James M. Atkinson

contributor to careful statistical modelling, the formulation of scientific questions and the relationship between design and inference.

For an SDR investigation Cox's most pertinent concern is the relation between an estimand and the way the observations were selected. A receiver that records only threshold-triggered windows creates a different sample from a receiver that preserves an uninterrupted band. The two may be compared only after the selection mechanism and target quantity are made explicit. In a negative survey, the absence of a reported alarm is conditioned on the signal family, sensitivity and valid exposure. No universal probability of absence follows from a single number. Conversely, carefully planned trials of known reference bursts can provide useful performance estimates without pretending that an entirely unknown emission population has been sampled.

The constructed peer intervention is therefore an exercise in statistical specification, not a retroactive judgement by Cox on modern instruments. His work supports attention to the analysis plan, conditioning, model checks and the difference between a retrospective explanation and a prospective test. A correct equation cannot rescue a poorly defined question. By including his historical perspective, the roundtable requires the examiner to describe what was measured, why the design is informative, and how the final claim responds to possible departures from its assumptions.

Sir Edward Victor Appleton

1892–1965. British physicist; Nobel laureate in physics, 1947. Sir Edward Victor Appleton's work on radio propagation changed the scientific understanding of the upper atmosphere and its importance to terrestrial

Copyright 2026, James M. Atkinson

communications. Born in Bradford, he studied at Cambridge and undertook experimental work associated with the Cavendish Laboratory. In the 1920s his measurements contributed decisively to the recognition of ionised atmospheric layers capable of returning radio waves to Earth, and subsequent investigations revealed the higher region associated with his name. His work provided practical foundations for radio-frequency planning and for understanding the variable paths that long-distance signals may follow. He held academic appointments in London and Cambridge, served in the British scientific administration and became Principal and Vice-Chancellor of the University of Edinburgh. He was elected to the Royal Society, knighted and awarded the 1947 Nobel Prize in Physics. The present discussion draws upon the significance of his field: the arrival of a radio wave at an antenna cannot invariably be read as the geographical direction to its transmitter. The modern SDR, forensic and source-attribution applications placed in his mouth are newly written teaching material. They should not be cited as Appleton's historical opinions or as descriptions of experiments he performed. His role is to insist that the Earth's propagation environment remains part of the measurement rather than a nuisance excluded by a tidy map. Editorial relevance also lies in the distinction between a reproducible laboratory transmission path and the variable propagation encountered outside the laboratory. Modern receiver software can refine numerical estimates, but a change of atmosphere can change the measured field before the numbers exist. The assigned question makes this physical limit central to the ethics of source attribution.

Copyright 2026, James M. Atkinson

Sir Harold Jeffreys

1891–1989. British mathematician, geophysicist and statistician. Sir Harold Jeffreys pursued a career spanning geophysics, astronomy, applied mathematics and statistical inference. Associated for much of his career with Cambridge and elected to the Royal Society, he became influential in the treatment of uncertainty and the use of probability to compare scientific explanations. His methods were particularly important in problems where indirect measurements had to be related to hidden physical quantities through mathematical models. The present fictional conversation draws on that intellectual setting to challenge careless movement between the likelihood of evidence under a hypothesis and the probability that a hypothesis is true after observing the evidence. A technically impressive correspondence between signals may provide some support for a particular physical-source proposition, but the strength and meaning of that support depend upon the competing proposition, the relevant population and the evidential model. Jeffreys is not being quoted as the author of modern forensic-reporting standards; the practical example is newly written. He serves instead as a reminder that conditional probabilities have direction, that unstudied alternatives cannot be silently eliminated and that experts ought not to insert the conclusion of a judicial or managerial decision where the scientific evidence supports only a narrower comparison. His contribution lends an appropriately rigorous close to the panel's discussion of attribution. The teaching objective is to separate the scientist's comparison of evidence under hypotheses from the decision-maker's eventual judgement about action or responsibility. Those judgements may use different premises, costs and standards. The distinction is especially

Copyright 2026, James M. Atkinson

important when a technically credible signal match is mistakenly presented as a numerical probability that a person committed an act. Sources and read scope. Question 007 The original dialogue, hypothetical case facts and numerical examples were written for this volume. The following are technical and biographical reference sources, not records of the speeches assigned to historical speakers. Consulted 9 November 2026. Sir Karl Raimund Popper

Karl Raimund Popper was born in Vienna in 1902 and died in 1994. The London School of Economics identifies Sir Karl Popper as the founder of its Department of Philosophy, Logic and Scientific Method in 1946 and describes his work on falsifiability, criticism, and the distinction between science and non-science. The institutional record supports the title Sir Karl used here. His inclusion rests on philosophy of scientific method, not on an asserted career in receiver engineering. No technical invention or later instrument specification is attributed to him in this biography. [B05]

The constructed role examines whether an evidential claim remains open to a relevant adverse observation. In this volume, that question arises when a receiver trace has several plausible explanations and the examiner changes settings to distinguish them. Popper's contribution asks whether the changes expose a genuine difference between predictions or merely produce another result that can be accommodated after the fact. The particular receiver examples belong to the author's present synthesis and to the technical models developed in the main chapters. They are not

Copyright 2026, James M. Atkinson

represented as Popper's own historical judgements about modern equipment.

This methodological role is deliberately limited. Philosophy does not supply the missing transfer function, calibration record, or probability model. It can, however, expose a claim that has become protected against every possible experimental result. The discussion therefore keeps engineering predictions, measurement conditions, and the interpretation of failed challenges distinct. Popper also addresses the legitimate use of an indeterminate category when a necessary premise remains unestablished. His task is to make that category criticisable rather than convenient. The result is a perspective on how the report can preserve disagreement and specify a useful next test without manufacturing unanimity or converting uncertainty into a universal refusal to draw conclusions.

Sir Martin Ryle

1918–1984. British radio astronomer; Nobel laureate in physics, 1974. Sir Martin Ryle was among the principal architects of modern radio interferometry and aperture synthesis. Born in Brighton, he studied at Oxford and worked on wartime radar before pursuing research at the University of Cambridge. His subsequent work with radio receiving systems and interferometric methods enabled increasingly detailed astronomical surveys, while establishing the importance of calibrated baselines and coherent measurements. As director of the Mullard Radio Astronomy Observatory, a Cambridge professor and later Astronomer Royal, Ryle helped turn radio astronomy into an exact experimental discipline with demanding instrumental foundations. He shared the 1974 Nobel Prize in Physics with Antony Hewish, the award specifically recognising Ryle's

Copyright 2026, James M. Atkinson

observations, inventions and aperture synthesis. For the present dialogue, his contribution provides an intellectual bridge between the geometry of an antenna array and the interpretation of a reconstructed direction. The case of an SDR direction finder near a building is a modern hypothetical scenario rather than any assertion about Ryle's historical work. The editorial emphasis on oscillator calibration, cable delays and model-dependent localisation is consistent with the measurement challenges encountered in radio interferometry, but the precise forensic doctrines in the question are original to this volume. His appearance therefore honours the methodological lineage without fabricating a transcript from the past. The editorial lesson is not that radio astronomy and building surveillance are identical practices. Their shared discipline is the need to understand phase, geometry, calibration and the information supported by sparse measurements. A precise reconstruction is valuable when its instrumental premises are available for challenge and re-examination, and misleading when the premises are assumed away.

Sir Robert Alexander Watson-Watt

Sir Robert Alexander Watson-Watt was a Scottish engineer and pioneer of radar whose work in the British scientific establishment combined experimental radio physics with the demands of operational detection. Born in Brechin, he studied at Dundee when the college was part of the University of St Andrews, and he developed interests in radio waves and meteorology. His work on atmospheric electrical disturbances and radio direction finding helped prepare the technical foundation for radar. During the 1930s he played a central role in the development of British aircraft-detection systems, and the resulting early-warning network became of exceptional

Copyright 2026, James M. Atkinson

importance in the Battle of Britain. He was elected a fellow of the Royal Society and was knighted for his wartime scientific contribution. The United Kingdom's public scientific and archival institutions maintain historical accounts of this work. [S8]

Within this newly constructed educational discussion, Watson-Watt asks whether nominally accurate hardware can support a negative-surveillance conclusion when the observation schedule may miss brief transmissions. His historical expertise supplies a pertinent conceptual standpoint: the operational value of a detector depends upon the event's arrival, the apparatus's opportunity to observe it, and the action that follows the indication. An electrical measurement which is extremely precise only at the moments when it is performed does not necessarily establish that no relevant event occurred between those moments. The dialogue deliberately avoids suggesting that he witnessed modern converter ENOB testing, contemporary digital sample retention, or current TSCM equipment. Instead, it uses a documented interest in rapid warning and radiolocation to interrogate a modern hypothetical concerning exposure probability, scanner duty cycle and the difference between a silent alarm system and an electromagnetically silent environment. His comments are original reconstruction, not an archival transcript.

Sir Ronald Aylmer Fisher

Sir Ronald Aylmer Fisher (1890–1962) was a British statistician and geneticist whose work was associated with Rothamsted Experimental Station and Cambridge. His historically documented areas of work include experimental design, likelihood reasoning and the statistical comparison of competing hypotheses. The relevance of that intellectual tradition to this

Copyright 2026, James M. Atkinson

textbook is interpretive rather than personal: no historical endorsement, eyewitness evidence, modern SDR testing, or authenticated quotation is attributed to him. The constructed discussions draw upon this methodological background while evaluating contemporary hypothetical instrumentation. In particular, the associated questions 017 explore mechanisms and evidence in which noise figure characterises a stipulated reference temperature and linear noise transfer, not the probability of detecting an arbitrary burst in a changing field. The panel uses his named contribution to ask a specific and falsifiable question: how should an investigator declare the sampling scheme and distinguish exploratory discovery from preplanned confirmation? To answer responsibly, one must examine noise factor, equivalent noise temperature, effective bandwidth, kurtosis, false-alarm rate and occupied-time exposure, rather than treating the apparatus readout as a self-authenticating account of physical origin. One illustrative circumstance is that an input-terminated receiver shows a quiet floor, although antenna-connected captures display rare, very large positive excursions. A competing interpretation is that thermal amplifier noise and non-gaussian environmental interference may share average power while differing sharply in their detection tails. This contrast should be tested by compare terminated-input noise measurements with calibrated antenna states, time-tagged pulse statistics and detector thresholds over stratified intervals, with adverse observations and calibration states preserved. The biographical facts establish professional chronology and domain of scholarship; the imagined question and answer are editorial devices used to teach the distinction between direct observation and model-dependent inference. No claim is made that the individual employed,

Copyright 2026, James M. Atkinson

approved, or could have anticipated the exact modern instrumentation named in this educational exercise. The reader must rely on the measured variables, explicit assumptions, and the validity of the controlled comparison rather than on the prestige of the historical contributor.

Historical expertise and source concordance: Experimental design, statistical likelihood and biological statistics. Role in receiver noise and observation-schedule exchanges is a methodological reconstruction, not historical technical testimony. Independent historical source: https://mathshistory.st-andrews.ac.uk/Biographies/Fisher/

Solomon Kullback

Solomon Kullback (1907–1994) was an American mathematician, statistician and cryptanalyst. The contribution relevant to this manuscript is information divergence, statistical discrimination, uncertainty and the difference between class models.

Kullback's statistical work offers a disciplined language for distinguishing probability distributions, but the chosen model determines what its numerical divergence actually means. In a radio-source classification problem, one can compare a suspected waveform with alternatives by a divergence measure while still failing to identify its physical origin. He can interrogate reference distributions, independence assumptions, rare classes and the consequences of short records. An appropriate application would calculate or simulate the divergence between two specified observation models and test how calibration errors alter it. An attractive number cannot replace physical corroboration.

In the planned Question 079, the concrete issue is: How should false-alarm probability be controlled across millions of spectral comparisons? An appropriate proposed experiment is to run calibrated noise-only simulations preserving channel covariance, then compare maximum statistics with

Copyright 2026, James M. Atkinson

nominal single-bin thresholds. The corresponding interpretive caution is that a probability of one in a million per bin is not a one-in-a-million probability for the largest of many bins.

This contributor will be evaluated against the concrete distinction between separate per-test significance, family-wise error, false-discovery rate, effective trials under correlation and post-selection inference. and a probability of one in a million per bin is not a one-in-a-million probability for the largest of many bins. rather than against an invented claim of personal experience with the specified apparatus.

Limits of attribution: Statistical distance can rank hypotheses under assumptions, but it is not proof of a particular physical emitter or private message. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

W. Edwards Deming

W. Edwards Deming was born in 1900 and died in 1993. Trained in mathematical physics, he became an influential statistician, teacher and adviser whose work connected variation, measurement, organisational learning and the improvement of processes. He received a doctorate from Yale University and developed strong intellectual connections with Walter A. Shewhart's work in statistical process control. His professional influence extended across American and Japanese industry, most famously through post-war teaching and consulting activities that linked technical quality methods with management responsibility. Institutional biographies from

Copyright 2026, James M. Atkinson

the W. Edwards Deming Institute and the American Society for Quality provide the principal historical foundations for this account.

For the present educational dialogue, Deming's relevance lies in the institutional interpretation of a calibration record. A laboratory can possess excellent measurement equipment and still produce unreliable evidence if its incentives favour suppressing failed tests, discarding inconvenient data or reporting only the final result after repeated adjustment. Deming's documented emphasis on systems and improvement provides a framework for examining such failures without reducing them to the moral weakness of an individual technician. His constructed peer challenge asks whether the quality of a laboratory's evidence can be evaluated separately from the organisational arrangements that produce, preserve and disclose it. The point is not to attach Deming's name to a modern forensic standard he did not write. Rather it is to use his documented statistical and managerial contributions to test whether a measurement-assurance programme is designed to learn from instability or merely to manufacture an appearance of conformity. His thought is particularly pertinent where the instrument is reliable only when its operators can preserve adverse evidence without institutional penalty.

Walter Andrew Shewhart

Walter Andrew Shewhart was an American physicist, engineer and statistician, born in New Canton, Illinois, in 1891. His academic preparation included study at the University of Illinois and doctoral work at the University of California, Berkeley. He joined Western Electric in 1918 and became a foundational figure in statistical quality control. His development of control-chart thinking helped industrial investigators distinguish ordinary

Copyright 2026, James M. Atkinson

process variation from signals that a process had changed. That achievement is documented in standard historical accounts of statistical engineering. The present dialogue applies his intellectual principles to modern digital receiver records; it does not claim that he designed contemporary FFT detectors or investigated contemporary technical surveillance systems. [B2]

Shewhart's importance for this question lies in his attention to the process which produces measurements. An electronic receiver can have stable hardware at one moment and a different effective detection characteristic after changes in gain, threshold estimation or interference. A sequence of alarm records may then mix observations taken under different operating conditions. Shewhart's perspective directs attention to those state transitions and to whether apparently repeated alarms reflect distinct physical events or the continuing effect of a system with memory. The correspondence with industrial process control is methodological, not a declaration that every radio signal should be interpreted using an ordinary factory control chart.

In the fictional roundtable, Shewhart asks that event-clustering procedures be tested against deliberately varied challenge bursts, including cases near the threshold where a rule is likely to fail. He also stresses that an algorithm selected after viewing the field evidence must not be described as though its reported detection probability were validated independently. Such distinctions are central to defensible scientific reporting. His intellectual persona is suited to a discipline in which reproducibility, transparent operating conditions and honest records of unfavourable observations are as important as the apparent precision of a numerical

Copyright 2026, James M. Atkinson

output. The biography rests on documented professional history, while the exchanges remain newly authored educational prose.

Historical expertise and source concordance: Statistical quality control, control charts and distinguishing process changes from stable variation; not an authority on late digital receiver standards by personal historical experience. Independent historical source: https://asq.org/about-asq/honorary-members/shewhart

William Feller

William Feller (1906–1970) was a Croatian-born American mathematician whose contributions to probability theory influenced the analysis of random events, stochastic processes and limiting behaviour. His widely read works on probability theory joined mathematical precision with carefully developed examples. His career took him through European mathematical institutions and eventually to academic work in the United States. The historical Feller did not research digital spectrum monitors, but his methods are particularly valuable when a technical report relies on rare-event probabilities or the mathematical properties of long observation sequences.

A monitoring team might wish to estimate the probability of missing a short emission, the frequency of false alarms or the distribution of waiting times between detected events. Such quantities depend not only on the nominal detection probability but also on event duration, temporal dependence, sampling policy and censoring. Counting a hundred threshold crossings does not necessarily mean a hundred independent occurrences. Likewise, a long run of negative observations cannot be interpreted without defining what events would have been visible to the detector. Feller's probability tradition presses the investigator to identify the random process, the event being counted and the assumptions under which an approximation is valid.

Copyright 2026, James M. Atkinson

The imaginary peer challenge belongs to probability, not to microwave circuit design or instrument certification. His perspective supports the careful use of binomial, Poisson or renewal models only when their respective premises have been examined. A model can be illuminating while still failing as a description of a deliberately adaptive transmitter or a receiver that changes state in response to previous detections. The present-day engineering author must therefore combine Feller's mathematical principles with evidence about actual capture windows, thresholds and system behaviour before drawing a forensic conclusion.

Historical reference consulted: https://mathshistory.st-andrews.ac.uk/Biographies/Feller/

William Ralph Bennett

William R. Bennett (1904–1983) was an American communications researcher whose work was associated with Bell Telephone Laboratories. His historically documented areas of work include quantisation-noise and telecommunications signal analysis. The relevance of that intellectual tradition to this textbook is interpretive rather than personal: no historical endorsement, eyewitness evidence, modern SDR testing, or authenticated quotation is attributed to him. The constructed discussions draw upon this methodological background while evaluating contemporary hypothetical instrumentation. In particular, the associated questions 024, 025, 029 explore mechanisms and evidence in which dnl and inl are code-domain static specifications whose dynamic spectral consequences require separate experiments. The panel uses his named contribution to ask a specific and falsifiable question: how should an investigator distinguish idealised stochastic error laws from input-dependent spurs and overload signatures? To answer responsibly, one must examine LSB size, DNL, endpoint INL, best-

Copyright 2026, James M. Atkinson

fit INL, missing-code count, temperature drift and calibration residuals, rather than treating the apparatus readout as a self-authenticating account of physical origin. One illustrative circumstance is that some codes are noticeably wider than others, and a best-fit transfer curve differs from an endpoint fit. A competing interpretation is that differential code-bin error, integral transfer curvature and genuine analogue amplitude variation can all perturb a reported weak-signal level. This contrast should be tested by acquire a controlled histogram and sine-wave series across temperature, input frequency, and stimulus amplitude with documented reference-line conventions, with adverse observations and calibration states preserved. The biographical facts establish professional chronology and domain of scholarship; the imagined question and answer are editorial devices used to teach the distinction between direct observation and model-dependent inference. No claim is made that the individual employed, approved, or could have anticipated the exact modern instrumentation named in this educational exercise. The reader must rely on the measured variables, explicit assumptions, and the validity of the controlled comparison rather than on the prestige of the historical contributor.

William Redington Hewlett

Among the historical authorities newly considered for Volume 11 is William Redington Hewlett (1913–2001). The documented career is that of an American electronics engineer; resistance-capacitance oscillator and electronic instrumentation. Its appropriate scope here is oscillator design, precision instrument development, frequency measurement and experimental engineering practice.

Copyright 2026, James M. Atkinson

Hewlett’s oscillator work was instrumental in the development of practical electronic test equipment. His contribution is best placed at the intersection of circuit design and the need to measure what instruments actually deliver. Consider a gate-time experiment in which an oscillator drifts during a very short carrier burst. A displayed frequency estimate will depend on the count strategy and the accepted measurement window. A historically sensitive intervention would insist upon calibrated standards, identified switching states and direct tests of the output waveform. He should not be used as an authority for modern legal evidence standards.

The contribution can be tested against Question 057: How do frequency-counter gate time and dead time bias observations of a drifting burst carrier? There, the proposed discriminating experiment would apply gates of several durations to a programmed chirp and compare recovered centre frequency against the original waveform chronology. The stated failure mode is equally important: an apparently precise counter display can average over the very drift the investigator must describe.

Limits of attribution: He is relevant to analogue measurement architecture and circuit behaviour, not to forensic legal opinions beyond instrument competence. This is a modern scholarly introduction, not a transcription of historical speech. Supporting institutional and professional references are recorded in the editorial contributor research register.

William Sealy Gosset

William Sealy Gosset (1876–1937), best known by the pseudonym 'Student', was a British chemist and statistician whose mathematical work grew directly from industrial experiments. Educated at Winchester College

Copyright 2026, James M. Atkinson

and New College, Oxford, he joined the Guinness brewery in Dublin and became concerned with drawing useful conclusions from small numbers of observations. His work helped establish the Student t-distribution and the practical treatment of small-sample uncertainty. His historical achievement is particularly pertinent to applied engineering, where carefully controlled experiments may be costly and a large independent sample is not always available.

In the roundtable, Gosset's proper concern is the amount of evidence actually contained in a finite sequence of receiver tests. A dozen successful detection trials can be valuable, but they do not establish the same performance bounds as thousands of independently prepared trials. When the variance is estimated from a small sample, uncertainty in that variance cannot simply be ignored. Moreover, repeated measurements of one uninterrupted burst may be highly dependent despite producing a large numerical sample count. His statistical approach encourages the examiner to describe the unit of replication and to avoid representing an overly narrow interval as proof of receiver reliability over untested conditions.

The reconstructed dialogue does not attribute to Gosset any knowledge of present-day ADC datasheets, spectrum-monitoring software or technical-surveillance investigations. It applies the legitimate small-sample logic of his work to modern engineering questions while leaving the electronics to experts in that discipline. His historical role is also a reminder that sound statistical methods arise from practical problems: measurements should be designed around the decision they are meant to support, and the resulting conclusions must state the conditions under which the chosen approximation has genuine evidential force.

Copyright 2026, James M. Atkinson

Historical reference consulted: https://mathshistory.st-andrews.ac.uk/Biographies/Gosset/

Historical expertise and source concordance: Chemist and statistician at Guinness, known for small-sample statistical inference under the pseudonym Student; methodological analogy should not be described as radio engineering expertise. Independent historical source: https://mathshistory.st-andrews.ac.uk/Biographies/Gosset/

William Thomson, Baron Kelvin

William Thomson, Baron Kelvin of Largs (1824–1907), was born in Belfast and became one of the nineteenth century's most influential British mathematical physicists and experimental engineers. He entered the University of Glasgow as a child and held its professorship of natural philosophy from 1846. His work extended across thermodynamics, electrical measurement, electromagnetic theory and practical telegraph engineering. He is particularly associated with an absolute scale of temperature and with scientific instruments whose construction and calibration permitted weak electrical effects to be distinguished from the limitations of earlier apparatus.

The transatlantic telegraph cable offered Kelvin a demanding field problem in which electrical theory, transmission-line behaviour, instrumentation and economic consequences met. He made important contributions to the understanding of cable signalling and to the development of sensitive receiving instruments, including the mirror galvanometer and siphon recorder. Their historical significance is the insistence that the physical system and the receiving instrument must be analysed together. A recorded waveform could be delayed or distorted by the transmission path, and improvements in measurement could alter the apparent behaviour of the same remote source.

Copyright 2026, James M. Atkinson

Kelvin was not familiar with present-day analogue-to-digital converters or software-controlled calibration. His role in this constructed dialogue is instead a historical point of comparison for modern metrology. A calibration established under one load, temperature, frequency or receiver configuration cannot simply be transported to a different state. Trends in gain and timing must be tied to traceable reference conditions and, where appropriate, a stated uncertainty. The modern numerical examples are separately authored pedagogical illustrations and not historical exercises carried out by Kelvin. This distinction is necessary both for scholarly accuracy and for the integrity of the fictional expert discussion.

Historical-source qualification: the directory identifies all speaking contributors, but the relevance notes are editorial interpretations of historical research, not evidence that any participant encountered present-day SDR equipment or took part in this fictional discussion. Full bibliographical verification remains a separate publication requirement.

End of contributor biographies. The formal moderated discussion begins with Question 001 on the following page.

QUESTION 001

Copyright 2026, James M. Atkinson

When may a receiver observation become an evidential claim?

Source: V011_Roundtable_Q001-Q011_CP011_Integrated_Candidate(2).docx | Recovered substantive manuscript. Constructed educational dialogue.

Constructed educational dialogue. The speeches below are newly authored, not historical quotations or a transcript. Modern cases and inferences are the author's applications of the cited manuscript material.

Dr. James M. Atkinson

Opening question

Mr Weston, can you comment on the conditions under which a receiver observation becomes a measurement, and on the further conditions required before that measurement can support an evidential claim? Our question is deliberately prior to the choice of receiver. A narrow line on a spectrum display, a sequence of stored samples, and a conclusion concerning an external source are different objects of knowledge. The first can be persuasive without the second being complete; the second can be intact without the third being justified. We shall examine those distinctions through an expressly hypothetical acquisition, not through an invented account of a field engagement. The receiver admits an identified band, preserves a stream of samples, and reports intermittent activity. Its operator wishes both to describe the activity and to exclude other activity during intervals without detections. [V1, V16]

The case leaves several matters open. We do not yet know whether the displayed amplitude refers to the antenna terminals or to a later boundary. We do not know whether an automatic gain change occurred immediately before the candidate event. The data format is known, but the continuity of

Copyright 2026, James M. Atkinson

its sample sequence has not been demonstrated. A second display appears to corroborate the first, although the two observations may share an antenna network, reference clock, or processing history. These are not allegations that the result is wrong. They identify propositions that a confident report would otherwise have to assume. Our task is to convert those assumptions into observations, justified restrictions, or explicit qualifications.

I invite the five principal respondents to examine successive boundaries rather than repeat a general appeal for caution. Mr Weston will consider the physical measurement and its reference. Dr Nyquist will address what the acquisition preserves and what its transformations make ambiguous. Dr Shannon will distinguish a retained representation from the information needed for a particular question. Professor Neyman will examine the trial population and the meaning of validated detection performance. Sir Karl Popper will consider how competing explanations can be challenged without turning every adverse observation into a new excuse. Seven colleagues will question those positions, with each question answered before the discussion passes onward.

The inherited chapters provide our common technical vocabulary. The discussion does not impute knowledge of present instruments to historical participants, and none of its speech is offered as a historical quotation. Modern applications and experimental proposals are newly authored for this volume. We shall not ask an instrument certificate to settle source identity, nor ask statistical terminology to repair an unobserved physical boundary. Equally, we shall not make perfect knowledge a prerequisite for

Copyright 2026, James M. Atkinson

every useful finding. A limited conclusion can be rigorous when its premises and remaining alternatives are stated. [V1, V10, V16]

At the end, the panel must identify what the record would need to contain for another examiner to reproduce the stated analysis and to contest its interpretation. It must distinguish a measurement that requires a correction from one whose proposed inverse has lost uniqueness. It must also identify circumstances in which a negative result is indeterminate rather than reassuring. Mr Weston, may I first invite your account of the physical comparison and the discipline that should govern its passage into a report?

Copyright 2026, James M. Atkinson

Edward Weston

The physical comparison and its declared boundary

Dr. Atkinson, thank you. My observation is that a measurement begins with a comparison whose physical meaning survives the instruments used to perform it. The visible indication is the conclusion of that comparison, not its complete definition. In the present case, an amplitude value becomes interpretable only after we identify the point at which the quantity is claimed, the conditions of loading there, and the transformations between that point and the indication. A correction is an assertion about those transformations. Its presence in software does not establish that the asserted relationship held when the event was acquired. I would therefore begin by tracing the connection from the input boundary to the retained result, marking which relationships were measured and which were merely selected from nominal settings. [V1]

Consider a cable correction derived in a separate calibration. There is nothing objectionable about applying it where the relevant connection, frequency, loading, and environmental conditions remain within its supported use. The difficulty begins when a replacement adapter, changed routing, or different input state is treated as immaterial without examination. It may be immaterial for the proposed uncertainty; that is a conclusion to establish, not a privilege conferred by the component's small size. A physical drawing can help here, but only if it records the arrangement actually used. An elegant diagram of the intended system does not repair an undocumented change made while pursuing a transient.

I would next separate the identity of the reference from the applicability of the comparison. A reference can have a sound calibration history while

Copyright 2026, James M. Atkinson

the present transfer from it to the receiver remains defective. The operator must show how the reference reached the point being tested, which parts of the chain it traversed, and what it failed to traverse. A signal injected after a vulnerable stage can establish a downstream response without demonstrating the upstream stage's condition. That distinction is especially important when the reference appears normal during an interval in which the desired external signal could have been distorted earlier in the chain. The reference is not false; its evidential scope has simply been overstated. [V1, V16]

The same separation applies to repeatability. A stable indication gives evidence concerning stability under the conditions repeated. It does not independently establish the accuracy of a common correction, the absence of a common unwanted component, or the correctness of a frequency mapping. Repetition is powerful when it varies the circumstance that could create the error. Repetition without that variation can leave the most important explanation untouched. I would consequently record the physical reason why each proposed repeat is informative. Did it alter a loading condition, challenge an internal source, test a different gain state, or merely demonstrate that the same stored data produce the same display?

Dr. Atkinson, the hypothetical receiver should also be examined across its transitions, not solely in settled states. Suppose the stored event follows a large disturbance and the displayed trace has returned to an ordinary appearance. The relevant question is whether the weak-signal measurement has recovered, not whether an indicator looks familiar. We can propose a controlled probe at a declared boundary, observe its response before and after the disturbance, and compare that response with the acceptance

Copyright 2026, James M. Atkinson

condition for the intended measurement. A probe that tests amplitude recovery does not necessarily test phase recovery. The claim must follow the property actually examined, while the untested properties remain separate. [A1]

A useful field record would connect each reported interval to its configuration and validity state. This need not become an administrative burden detached from the physics. It is the minimum information required to distinguish a change in the external signal from a change in the instrument's response. Unknown transitions should remain visible. Joining two accepted records across an unresolved interval may create the appearance of continuous observation without providing it. A reader should be able to see both what was measured and where the experiment ceased to support the proposed interpretation.

There is also a boundary between correcting an indication and reconstructing an input. Where the measurement relationship is sufficiently characterised and reversible for the specified quantity, a correction can be justified. Where several materially different inputs produce the same retained output, an apparently precise inverse must depend on additional assumptions. Clipping provides an instructive example already developed in the volume: numerical rescaling can change the surviving values without uniquely recovering the amplitudes that exceeded the range. The operator should state what remains measurable, rather than treating every compromised record as either wholly useless or fully restored. [V10]

My proposed acceptance rule is therefore practical. State the quantity and boundary; identify the applicable comparison; demonstrate the relevant operating state; preserve the observations supporting the correction; and

Copyright 2026, James M. Atkinson

distinguish that corrected quantity from a causal account of the source. The report should be strong where these links are strong and restricted where they are not. Precision is not achieved by refusing every conclusion, but by preventing a conclusion from quietly extending beyond its comparison. Professor Bridgman, may I invite your question about whether this account defines the quantity through an operation or merely gathers conditions around an undefined name?

Percy Williams Bridgman

Peer question 1 to Edward Weston

Mr Weston, thank you. Your insistence on the physical comparison is persuasive, but I should like to test the identity of the quantity being compared. Suppose two examiners both report the amplitude of the same burst. One reports a peak taken after a narrow analysis filter; the other reports an average over a retained interval. Both possess calibrated references and reproducible procedures, yet their numbers differ. It would be misleading to begin by treating that difference as an instrumental disagreement. The operations may define different quantities. Conversely, two differently implemented procedures might be intended to estimate the same quantity but require a demonstrated relation before their results are combined. How would you require the examiner to distinguish these cases without reducing measurement to an arbitrary collection of operational definitions? In particular, what should remain invariant when a procedure is changed, and what evidence would establish that the revised procedure still addresses the original question?

Copyright 2026, James M. Atkinson

Edward Weston

Answer to Percy Williams Bridgman

Professor Bridgman, I would first require the intended comparison to be stated independently enough that the operations can be judged against it. The word amplitude is insufficient. The record should identify the waveform quantity, reference plane, bandwidth, time interval, and estimator. Your peak and average can then be recognised as different results rather than forced into spurious agreement. Their relation may be calculable for a specified waveform and filter, but that relation should not be assumed for an unknown burst. A common label cannot supply the missing model. [V1, V10]

The invariant is therefore not necessarily the numerical indication. It is the declared quantity or proposition that the procedures are intended to estimate. A changed filter may preserve a calibrated integrated-power result under identified conditions while altering the peak and timing of a transient. To establish equivalence, I would compare the procedures with signals that exercise those conditions and preserve the transformations needed to refer their results to the common quantity. A single comfortable calibration tone would not settle a claim about arbitrary bursts.

Dr. Atkinson has asked us to identify an evidential boundary rather than formulate a universal measurement philosophy. At that boundary, an examiner can state that the procedures agree for a tested signal class and uncertainty requirement, while leaving their equivalence elsewhere unestablished. This is neither arbitrary operationalism nor a promise of access to an unconditioned physical

Copyright 2026, James M. Atkinson

reality. It is a controlled correspondence between an intended quantity and an implemented procedure. The definitions permit the comparison to be criticised; the experiments determine how far the correspondence has been demonstrated.

I would retain both results where they answer different useful questions. The peak may inform an overload assessment, while the interval average may characterise another aspect of the event. Their separation strengthens the report by preventing one result from being borrowed to support the other's claim. Where a revised procedure genuinely supersedes an earlier one, the record should preserve the reason and the transformation, not merely replace the old number. Dr Shewhart, may I invite your challenge concerning the stability evidence required before we treat such a correspondence as continuing through a long acquisition?

Walter Andrew Shewhart

Peer question 2 to Edward Weston

Mr Weston, I appreciate that distinction. My concern is the passage from an acceptable comparison on one occasion to a claim that the same comparison governed a later interval. Suppose a reference check is made before a survey and another after it, and both fall inside the chosen acceptance limits. During the survey, however, the receiver warms, changes gain, and encounters unusually strong signals. The endpoint checks do not reveal every intervening state. A trace might also be stable because an automatic process has suppressed variation, not because the underlying response remained unchanged. What evidence would justify continuing to use the original calibration across the interval, and when

Copyright 2026, James M. Atkinson

should a change become a reason to divide the record? I am particularly interested in how you would avoid treating every fluctuation as a fault while also avoiding an unsupported inference of stability from two satisfactory endpoints, especially when the intervening acquisition contains unlogged automatic changes.

Edward Weston

Answer to Walter A. Shewhart

Dr Shewhart, the endpoint checks establish endpoint facts, and interpolation between them is a model that requires its own support. I would not present the absence of an endpoint discrepancy as proof that every intermediate state remained acceptable. The experiment should first identify which changes can materially affect the intended quantity. If gain selection, temperature, or a preceding overload can alter the applicable transfer, the acquisition should record those states with sufficient timing to associate them with the observations. Where an important state is unknown, that interval should be qualified rather than assigned the most convenient correction. [V1, A1]

It is equally important not to turn a list of possible influences into a declaration that the instrument is always unfit. A characterised state range may justify continued use without continuous recalibration. The question is whether the present observations fall within that demonstrated range, including its uncertainty and response history. A change within the range may require no special treatment; a change outside it may require a new correction, a waiting interval, or rejection

Copyright 2026, James M. Atkinson

of a particular measurement. These actions should follow previously stated criteria when practicable.

Dr. Atkinson, I would divide the record when the interpretation changes, not merely when a display line twitches. A known gain transition with a supported correction can be retained as a distinct state. An unresolved transition might remain usable for a coarse detection while failing a precise amplitude comparison. The validity label should therefore refer to the claimed measurement. It need not declare every recorded sample universally valid or universally worthless.

The proposed evidence is a combination of characterisation, state logging, and appropriately placed checks. Each supplies something the others lack. Characterisation supports a relationship, logging identifies where it was applied, and checks can reveal departure from expected behaviour. None should be allowed to stand silently for all three. I would preserve their disagreements because those disagreements can identify the boundary of the claimed result. Dr Nyquist, may I now pass the discussion to you and ask how the sampling and frequency mapping can impose further limits even when this physical comparison has been competently established?

Copyright 2026, James M. Atkinson

Harry Nyquist

Sampling preserves a conditional representation

Mr Weston, thank you for establishing that boundary. Dr. Atkinson, I would distinguish the existence of a digital record from the recoverability of the analogue quantity that the record is intended to represent. A sequence of numbers can be preserved exactly while the process producing it remains ambiguous. Sampling maps admitted input behaviour into a discrete representation. The useful question is not whether the converter generated many samples, but whether materially different admitted inputs can produce the same recorded evidence for the question under examination. The volume's treatment of aliasing makes this distinction explicit. The analogue band selection and the actual sampling arrangement are part of the meaning of the record. [V10]

A frequency label cannot remove an ambiguity created before the label was assigned. Suppose a component is retained at a stable digital frequency. That observation does not by itself identify a unique external frequency if more than one admitted input band could map there. The appropriate examination varies the conditions that distinguish those possibilities within the safe and authorised limits of the equipment, such as the admitted analogue band or the sampling configuration, and records the predicted mappings before inspecting the result. This is a test of competing explanations, not a ritual performed merely to obtain a second attractive trace. A persistent line may remain entirely reproducible while its original frequency is misidentified.

The word actual is essential in this account. A requested sample rate, a menu selection, and a verified timing relationship are different records. The

Copyright 2026, James M. Atkinson

operator may legitimately begin from the instrument's configured rate, but the evidential claim should identify whether that rate was measured, nominal, or subject to an uncertainty model. A local oscillator and a sampling clock can enter the frequency interpretation in different ways. Replacing their separate roles with one generic statement that the receiver was synchronised conceals the relationships on which a frequency or timing comparison depends.

Continuity presents a second boundary. A file with the expected number of bytes need not contain the expected succession of physical sampling instants. Missing, duplicated, reordered, or restarted blocks can affect interpretation even when each surviving value lies within the permitted numerical range. A continuity record should identify source indices or an equivalent verifiable relation, rather than infer uninterrupted observation from the smooth progress of a playback cursor. Where gaps are known, the analysis must preserve them. Interpolation may create a convenient display, but it must not be counted as an additional observation of an event that was not captured. [V10, A1]

The third boundary concerns transformations after sampling. Mixing, filtering, and decimation can be sound operations, yet their output is a particular representation with a particular history. Its frequency origin, retained phase, response delay, initial state, and numerical scale must be identified to support a later comparison. The source record may permit those choices to be repeated or changed. A derived stream may not. Therefore the analyst should distinguish what can be recomputed from retained data from what would require a new acquisition. A changed

Copyright 2026, James M. Atkinson

analysis window can answer a new question about preserved samples; it cannot recover an analogue band that the front end rejected.

Dr. Atkinson, this account also changes the interpretation of nominal resolution. A large digital word describes a representation. Whether small changes in that representation correspond to recoverable input differences depends on the complete acquisition and the error processes relevant to the measurement. Arithmetic can preserve fractional results from an average without proving an equal improvement in every aspect of analogue performance. Likewise, a high aggregate sample rate can support a denser sampling grid without establishing freedom from mismatch, aliasing, or common disturbances. These are separate claims, and the proposed validation should keep them separate. [V10]

I would test the receiver with deliberately varied but controlled inputs chosen to challenge the proposed mapping. Move a known signal across relevant band boundaries, change the input amplitude within the claimed operating range, examine short records after state changes, and compare the retained output with the declared transformation. The point is not to simulate every possible environment. It is to find cases that expose the assumptions essential to the intended use. A test selected only because it is easy to reproduce can demonstrate repeatability while leaving the decisive ambiguity untouched.

My conclusion is consequently narrower and more useful than the assertion that digitisation preserves the signal. It preserves a representation under specified admission, timing, range, and processing conditions. The examiner must identify which properties remain recoverable and which distinctions have been lost or require additional information. This gives the

Copyright 2026, James M. Atkinson

later statistical analysis an honest observational basis. Otherwise, even impeccable calculations may describe a variable different from the one named in the report. Dr Bode, may I invite your question concerning the relationship between this sampled description and the dynamic states of the analogue network that precedes it?

Hendrik Wade Bode

Peer question 3 to Harry Nyquist

Dr Nyquist, thank you. Your account makes the sampling boundary explicit, but a receiver also carries memory in its filters and control loops. Suppose a burst arrives after a strong input has altered an automatic gain state. The recorded samples are continuous, the clock is well characterised, and the digital transformation is correctly documented. Yet the physical transfer during the burst is not the same as the transfer measured with a steady calibration signal. A frequency-domain response established in a settled condition may not predict the transient. Would you regard this as an error in the sampling representation, an inadequacy in the analogue model, or an ambiguity that belongs to both? More practically, what should the record contain to distinguish a changed source waveform from the receiver's changing response without assuming that a convenient steady-state correction remains valid throughout the event and across the preceding recovery history?

A further constraint follows from the conversion of an observed receiver indication into a bounded evidential proposition. The emitter identity, analogue reference-plane voltage, and activity outside the observed aperture remain outside the direct observation. If the examiner reports only those cases in which the indicated feature agreed with the

Copyright 2026, James M. Atkinson

preferred model, what correction would you require to the exposure denominator, alternative-hypothesis analysis, and reproducibility account?

Harry Nyquist

Answer to Hendrik W. Bode

Thank you for that question. Dr Bode, I would locate the inadequacy in the claim being made about the chain rather than force every problem into one stage. The samples can faithfully preserve the output of a changing analogue system while failing to identify its input uniquely. A correct description of the sampling process does not supply the missing state of that analogue system. Equally, a valid analogue model cannot repair undocumented sample gaps. The stages are distinct, but the final inference depends on their combined description. That is why the volume begins with the configured measurement system rather than the converter in isolation. [V1, V10]

The record should preserve the state information and preceding history required by the model used for correction. If a transient model has been identified and tested over the relevant operating range, the analyst can examine whether the present event satisfies its conditions. If only a settled response is known, applying it during a transition is an extrapolation. Its status should be explicit. A better-looking corrected pulse does not establish that the extrapolation was valid, because several different input histories may explain the same changing output.

Copyright 2026, James M. Atkinson

Dr. Atkinson, one useful proposed experiment is to compare a known probe through both settled and deliberately disturbed states, retaining the chronology rather than merely collecting final amplitudes. That experiment should examine the quantity at issue. A recovery criterion for power does not establish the recovery of phase or a trigger's event timing. Nor does a downstream probe certify an untested upstream path. The experimental boundary remains as important here as the sampling boundary.

Where the necessary state is unavailable, I would preserve the narrower statement: the receiver output contained the reported feature under an unresolved transfer condition. That may justify further investigation without supporting a reconstructed source waveform. We should not erase the observation, but neither should we restore missing premises by assumption. Dr Shannon, may I invite you to consider what information must be retained for later, potentially unforeseen analytical questions, and why a larger recording or a wider numerical word does not automatically resolve the distinctions we have identified?

A further constraint follows from the conversion of an observed receiver indication into a bounded evidential proposition. I would add the following qualification to my answer. For quantitative interpretation, the distinction between signal power at the antenna reference plane and displayed power after digital processing must remain explicit. A numerical threshold has meaning only together with calibration uncertainty, analysis bandwidth, detector statistic and valid observation exposure. Overlapping Fourier windows do not

Copyright 2026, James M. Atkinson

create fully independent measurements merely by providing additional rows. The result should therefore be accompanied by a denominator tied to genuine measurement opportunities, an account of clipped or missing intervals and a description of the nuisance conditions under which the decision procedure was challenged. In this particular question, the controlled observation is a timestamped receiver output obtained with a declared configuration, whereas the material uncertainty concerns the emitter identity, analogue reference-plane voltage, and activity outside the observed aperture. Consequently the adversarial comparison ought to include a documented reference-source injection and independent measurement path and its failed as well as successful outcomes. I would not advise treating a change in the displayed indication as an authenticated physical attribution until its causal mechanism has been experimentally distinguished.

Copyright 2026, James M. Atkinson

Claude Elwood Shannon

Retained representation and the questions it can answer

Dr Nyquist, thank you. Dr. Atkinson, my observation is that the value of a retained representation is relative to a question and a model of the alternatives that matter. A large file can be inadequate for a question whose distinguishing information has been discarded. A much smaller record can be adequate for a narrowly defined comparison if the retained statistic is sufficient under its supported model. These propositions do not license indiscriminate compression. They require the examiner to state what later distinctions must remain possible and what assumptions make the selected representation adequate. The original acquisition and its derived products should not be treated as interchangeable merely because both produce recognisable spectra. [V1, V10]

Consider a record containing only averaged spectral powers. It can support questions about those powers within the estimator's conditions. It does not ordinarily retain every phase relationship or the precise ordering of short events that contributed to the average. A later request for coherent combination or burst timing therefore asks for information that the stored product may not contain. The issue is not that the product was badly designed. It may have been designed for another purpose. The defect arises when its purpose is silently enlarged after acquisition. A proper retention decision should make both the supported uses and the abandoned possibilities visible.

The same reasoning applies to broad acquisition. Capturing a wide frequency interval can preserve context useful for identifying strong inputs, simultaneous activity, and possible receiver artefacts. It does not itself make

Copyright 2026, James M. Atkinson

every weak component detectable. The analysis still depends on admitted noise, distortion, the signal's distinguishing structure, and the interval over which that structure can be used. The wider record may make a better subsequent test possible, but it does not guarantee that the test's premises hold. A statement about captured bandwidth should therefore be kept separate from a statement about achieved detection performance for a specified signal class. [V10, V16]

I would ask what alternatives the proposed data reduction preserves. If the immediate purpose is to detect a known waveform, a specialised statistic may be informative. If the purpose is to investigate an unexplained event whose model may change, retaining only that statistic can make the investigation dependent on the first hypothesis. This is a design choice with evidential consequences. A cautious workflow may preserve a suitable source segment and its context when a detector identifies a candidate, while maintaining a broader account of coverage and acquisition validity. Its adequacy still depends on whether the trigger captured the necessary prehistory and whether the recording path remained sound.

Dr. Atkinson, there is an important difference between documenting a transformation and demonstrating that it is reversible for the intended use. A complete account of an average tells the reader how values were combined. It does not in general allow every original value to be recovered. A checksum can identify the retained bytes without establishing that the desired physical information was ever represented in them. A reconstruction can be mathematically consistent with a stored product while remaining non-unique. The report must therefore separate reproducibility of a

Copyright 2026, James M. Atkinson

calculation, integrity of a file, and identifiability of the physical quantity. Their evidence overlaps, but none automatically supplies the others. [V1, A1]

A further complication is the temptation to regard a confident classification as an independent source of information. Suppose a processing system assigns an event to a familiar waveform family. That result reflects the retained observations and the classification rule. If two different physical mechanisms produce the same relevant observations, the label does not distinguish them merely by sounding more specific. Additional context, an independently informative feature, or a controlled experiment is required. The classifier can be useful without becoming an oracle. Its task, training or fitting conditions where applicable, and limits of discrimination should remain part of the measurement account.

For an auditable archive, I propose a chain of representations rather than one supposedly definitive file. Identify the original retained sample intervals, their acquisition state, the transformations used to derive each product, and the propositions each product supports. Preserve the relation between an event marker and the source interval from which it was calculated. Where information was deliberately discarded, record the operation and the reason. The archive then permits a later examiner to distinguish a legitimate new analysis from a claim that would require observations no longer available. This is a practical architecture for criticism rather than a demand to preserve everything indefinitely.

The physical and legal boundaries of acquisition remain controlling. An engineering ability to retain more does not decide what may properly be collected or how long it should be kept. Within the authorised purpose, however, the retention scheme should be assessed against the uncertainty

Copyright 2026, James M. Atkinson

of future analytical questions. The most defensible scheme is one whose losses are understood and whose remaining claims are explicit. Mr Hartley, may I invite your question concerning the relation between a wide representation, a limited observation interval, and the distinctions a receiver can actually support?

Ralph Vinton Lyon Hartley

Peer question 4 to Claude E. Shannon

Dr Shannon, thank you. The distinction between a representation's size and its usefulness needs a practical test. Suppose an operator claims that a larger converter word and a wider retained band together make a recording more informative in every relevant respect. Yet the analogue front end admits a strong unwanted signal, and the stored values have been rescaled after a range excursion. Another acquisition uses a narrower, well-characterised path and retains less data, but preserves the weak feature of interest without that excursion. I do not suggest that narrower is invariably better. I ask how the examiner should compare these records without turning bandwidth, numerical precision, or file size into a single misleading league table. What must be specified about the task and the admitted alternatives before one can say that the first record contains more useful evidence than the second for a specified conclusion about the admitted physical signal?

Claude Elwood Shannon

Answer to Ralph V. L. Hartley

Thank you for that question. Mr Hartley, the comparison must begin with the proposition to be resolved and the conditions under

Copyright 2026, James M. Atkinson

which the records were formed. If the weak feature is irreversibly obscured by a range excursion in the broad acquisition, its nominal representation cannot repair that loss. The narrower acquisition may then support a stronger conclusion about that feature while supporting weaker conclusions about activity outside its admitted band. Neither record is universally superior. They preserve different distinctions under different physical conditions. A single score would conceal precisely the trade-off the examiner needs to understand. [V10]

Dr. Atkinson, I would compare at least the relevant frequency and time coverage, the operating validity of each path, the uncertainty of the retained quantity, and the alternative explanations that remain distinguishable. Those are not interchangeable units to be added casually. A record can gain coverage while losing useful amplitude discrimination, or gain sensitivity to one class while excluding another. The comparison should state that structure rather than borrowing the best attribute from each arrangement and presenting the combination as an achieved instrument.

Your example also shows why the evidence record should distinguish the original values from subsequent scaling. A change in representation may be entirely legitimate and precisely documented, but it must not conceal an earlier loss. Where the raw record is retained, an examiner may challenge the processing. Where only the rescaled product survives, the extent of that challenge can be limited. Documentation makes the limitation visible; it does not abolish it. A comparison record should therefore state which claimed distinctions

Copyright 2026, James M. Atkinson

survive each acquisition, rather than assume that a common file format establishes equivalence between their physical information.

The appropriate conclusion may therefore be that the records are complementary. The broad record provides context for possible interferers, while the narrower record supports the specified weak-signal measurement. Combining them requires demonstrated timing and reference relationships, not merely placing two traces on the same screen. Professor Gabor, may I invite your question about how transient behaviour and the choice of representation affect the temporal and spectral claims that such an archive can sustain?

Dennis Gabor

Peer question 5 to Claude E. Shannon

Dr Shannon, I welcome the insistence on complementary records. A transient presents a particular difficulty because a representation that makes its spectrum convenient may obscure the chronology that gives the event its significance. A long analysis interval can combine several physical episodes, while a short interval can change the discrimination between nearby components. Display persistence can further suggest a duration that belongs to presentation rather than acquisition. If the same source samples permit several legitimate analyses, how should an examiner choose among them without selecting only the representation that appears to support a preferred explanation? Should the report preserve one standard view, a family of views, or the procedure by which the views were compared? I ask especially how a disagreement between views should be described when it reveals different sensitivities to the

Copyright 2026, James M. Atkinson

event rather than an error in either calculation, and when both views remain reproducible from the same retained observations.

Claude Elwood Shannon

Answer to Dennis Gabor

Professor Gabor, I would preserve the distinction between the event and the operations used to examine it. The source samples, where valid and available, provide a common observational record. Each analysis then answers a specified question through a declared transformation. The report should identify the time interval, window, filtering, averaging, and display conventions that materially affect the result. It should not imply that a displayed extent is a direct measurement of transmitter duration when the transformation itself can broaden or retain the event. [V10, V16]

Dr. Atkinson, one useful safeguard is to state the primary analysis rule before reviewing the disputed event, while permitting clearly labelled exploratory analyses afterwards. An alternative view can reveal a weakness in the original interpretation or suggest a further test. It should not silently replace the original rule and inherit its validation claim. Exploratory settings can be preserved as exploratory settings, with their selection history intact, while a later confirmatory analysis applies a separately justified rule to an appropriate record. Where several views address different properties, report those properties separately. A view useful for estimating integrated energy need not be the preferred view for locating an onset.

Copyright 2026, James M. Atkinson

I would retain the procedure of comparison as well as the views necessary to explain the conclusion. A long catalogue of pictures is not a substitute for identifying what each comparison tests. If two views differ because they combine different intervals, their disagreement may be expected. If they purport to estimate the same quantity under equivalent conditions and disagree beyond the stated uncertainty, that discrepancy requires investigation. The report should show the distinction rather than resolve it by selecting the visually more persuasive panel.

The archive should also preserve observations that weakened the preferred account. Otherwise, later review encounters a curated conclusion rather than a reproducible analysis. This is an argument for disciplined selection, not for indefinite accumulation of redundant outputs. Professor Neyman, may I pass the discussion to you and invite your account of how the declared analysis rule, the trial population, and the uncertainty of its validation constrain the meaning of a claimed detection probability?

I thank the questioning colleague for that important distinction. The chronology of the point at which an antenna-terminal indication becomes an evidential proposition is indispensable. Assume for a moment that a signal seen at the receiver output could have originated in a mixer or through a common-mode path. In that case, rearranging snapshots to create a smooth chart will conceal the sequence of instrumental changes. We should inject a stable reference into the same physical port and then substitute a termination, and treat time spent switching, settling or clipping as

Copyright 2026, James M. Atkinson

measured invalidity rather than as an unoccupied channel. The state record needs absolute input power, receiver gain history, detector threshold and independent antenna-side confirmation. If a known reference remains measurable whereas the disputed feature changes after the antenna path is isolated, the first obligation is to determine whether the apparent motion in the display arose from the receiver or from the observed field. I would repeat the initial configuration after the challenge to expose drift, and I would preserve the records that fail to match the opening measurement. An operator may fairly publish a difference between the two visits, but may not infer a unique intervening event when the acquisition supplied no valid samples at the relevant instant. The result must be reported as a chronological comparison under named operating states.

Copyright 2026, James M. Atkinson

Jerzy Neyman

Performance belongs to a defined experiment

Dr Shannon, thank you. Dr. Atkinson, I would begin by distinguishing a procedure's observed success in a set of trials from its performance in a specified population of possible trials. The former is a record; the latter is an inference. That inference requires a sampling or experimental model, including what changes between trials and what is held fixed. A long list of successful replays can demonstrate reproducibility of processing without establishing performance across changes in analogue noise, signal timing, receiver state, or propagation. The word trial therefore carries more responsibility than the presence of a numbered row in a table. [A1, N1]

Our hypothetical operator wishes to make both positive and negative claims. For a positive detection, the decision rule and its alternatives must be defined. An event crossing a threshold is not automatically a correctly identified external source. The validation should distinguish detection of a stipulated signal, classification of a waveform, and attribution to a physical mechanism. Their errors can differ, and success at one stage does not establish success at the next. A test programme that presents only familiar, favourable examples cannot validate unrestricted classification merely because the reported labels are consistently correct.

For a negative finding, the relevant experiment includes the opportunity to observe the signal. A sensitivity test performed while the receiver is settled and correctly tuned does not establish detection during a gap, a sweep elsewhere, or a recovery interval. The acquisition schedule and validity history must therefore enter the claim. One should not use the scheduled duration as though every instant supplied equivalent evidence.

Copyright 2026, James M. Atkinson

The proposed report should identify the signal class, the conditions represented in validation, and the actual intervals over which those conditions were supported. Unknown coverage is a missing premise, not a particularly quiet observation. [V1, A1]

Uncertainty in the performance estimate is equally important. Even when the trial model is suitable, a finite set of outcomes does not reveal an underlying probability without uncertainty. The appropriate interval or bound depends on the inferential method and its assumptions. A statement about the long-run behaviour of a confidence procedure is not identical to a posterior probability for a particular parameter. The report should use the interpretation belonging to the chosen method rather than move between them because both employ percentages. The supplied expansion already develops exact zero-failure and zero-event examples with their respective conditions; those calculations should remain attached to those conditions. [A1, N1]

Dr. Atkinson, I would also resist pooling convenient conditions into a single attractive average. Suppose most challenge signals are strong and continuous, while a smaller but important group consists of short, weak bursts near a channel boundary. An overall success fraction can conceal poor performance in that smaller group. The proper remedy is not invariably to insist on an enormous experiment. It is to identify the material conditioning variables and report the limits of what the design establishes. Where the data do not support a reliable estimate in a relevant region, that region remains a qualification rather than borrowing the average performance of easier cases.

Copyright 2026, James M. Atkinson

Dependence between observations must be examined for the same reason. Several overlapping spectral windows can share much of their input. Two detectors can share a noise estimate. Separate receivers can share a front end or disturbance. Treating their outcomes as independent may assign the evidence a strength that the experiment never supplied. Independence is a property of the adopted model supported by the arrangement, not a reward for counting different labels. Where dependence is material but incompletely characterised, the examiner should choose an analysis that recognises it or restrict the resulting claim.

The distinction between development and validation is particularly useful. During development, thresholds, filters, and exclusion rules may be adjusted in response to observations. That process can improve a detector, but the observations used to make the adjustments do not automatically supply independent confirmation of the selected procedure. A confirmatory test should assess the resulting rule under a defined design without quietly allowing further favourable revisions. Where revision is necessary, preserve the chronology and identify the resulting test as further development. The scientific value of the work does not disappear; only its proper description changes. [V16, A1]

My proposed conclusion is conditional rather than evasive. State the tested procedure, the trial population, the relevant acquisition state, the observed outcomes, the inferential method, and the uncertainty. Then state which field observations satisfy the conditions needed to use that result. This provides a rational basis for a strong claim where the evidence permits one and exposes the particular work needed elsewhere. It is more informative than an unqualified assertion of sensitivity and more useful than

Copyright 2026, James M. Atkinson

a general declaration that certainty is impossible. Professor Pearson, may I invite your question concerning how a predeclared rule can remain meaningful in a receiver that legitimately adapts during observation?

Egon Sharpe Pearson

Peer question 6 to Jerzy Neyman

Professor Neyman, thank you. The separation between development and validation is necessary, but the receiver in our case may employ an adaptive threshold as part of its intended operation. Its background estimate changes with recent observations, and an event can affect the estimate used for later decisions. Freezing a single numerical threshold would then test a different instrument from the one deployed. At the same time, allowing unrestricted adjustment after seeing each result would make a performance claim difficult to interpret. Where would you draw the boundary between legitimate adaptation inside a defined procedure and post hoc revision of that procedure? Please also consider a noise reference contaminated by a neighbouring signal. Can the adaptation be called validated merely because its code is fixed, or must the trial design separately exercise the circumstances in which its reference ceases to represent the tested cell and its nominal false-alarm interpretation consequently becomes questionable?

Jerzy Neyman

Answer to Egon S. Pearson

Professor Pearson, the object to freeze is the decision procedure, not necessarily a constant numerical threshold. A specified adaptive rule can be tested as a rule, including its state updates, reference

Copyright 2026, James M. Atkinson

selection, guard conditions, and response to previous observations. The validation then concerns that dynamic procedure under the conditions represented in the trials. It does not concern an imaginary stationary threshold. Conversely, altering the adaptation rule after inspecting favourable outcomes is a revision of the procedure and must be identified as such. This distinction allows adaptation without concealing the role of development data. [A1, V16]

A fixed implementation is necessary for some reproducibility claims but does not establish statistical validity. Your contaminated reference is a direct challenge to the background model. The trials should include the types of neighbouring activity, nonstationarity, and state change that matter to the intended application. A rule can be precisely implemented while its claimed false-alarm interpretation fails outside the reference conditions used to derive it. The appropriate outcome is a qualified operating domain or a revised rule followed by further validation, not the assertion that executable code makes its assumptions true.

Dr. Atkinson, the record should preserve enough of the adaptive state to reproduce the actual decision. Retaining only the tested cell's power while discarding the reference membership and threshold history can make a later review unable to reconstruct why a detection occurred. It also conceals dependencies when several decisions share a fluctuating reference. Those dependencies matter when one interprets a cluster of detections as repeated confirmation. The required record concerns the actual reference used, not merely the default reference-window setting listed in a software manual.

Copyright 2026, James M. Atkinson

I would therefore validate both ordinary operation and declared failure behaviour. The system should identify conditions in which its evidence is insufficient for the usual interpretation, rather than conceal every difficulty through a new threshold. A qualified or indeterminate interval can be a correct result. Sir Karl, may I invite you to examine how such restrictions can remain genuinely testable, and how an examiner should distinguish a legitimate refinement from a succession of qualifications that merely protects a preferred explanation?

Copyright 2026, James M. Atkinson

Sir Karl Raimund Popper

A conclusion must remain vulnerable to a relevant test

Professor Neyman, thank you. Dr. Atkinson, the central distinction is between restricting a claim because its evidence has a demonstrated limit and restricting it whenever an adverse observation appears. The first makes criticism more precise. The second can deprive criticism of any possible consequence. In this constructed receiver case, an examiner should state which observations would count against the proposed explanation and why the instrument could obtain them. A promised test is not severe merely because it is elaborate. It must expose a difference between the explanation and a relevant alternative under conditions that permit that difference to be observed. [V16]

Suppose the preferred explanation is that a displayed line originates from an external source. The alternative might involve a conversion product, a sampled alias, or an instrument emission coupled through an external path. A useful challenge would identify how the predicted observation changes when an appropriate part of the arrangement is changed. The result must be interpreted through the actual physical consequences of that change. Terminating an input, for example, can remove several pathways at once. Disappearance is therefore evidence about the changed arrangement, not automatically a complete attribution. The test becomes informative through its specified predictions and preserved conditions, not through a ceremonial act of disconnection. [V16]

Dr. Atkinson, I would also insist that a failed challenge remain part of the account. If an examiner tries several changes and reports only the one that appears to favour the preferred explanation, the reader receives a selected

Copyright 2026, James M. Atkinson

narrative. The omitted results may reveal a missing interaction, insufficient sensitivity in a comparison path, or an unstable system state. They might also weaken an alternative explanation. In either direction, their value depends on preserving the sequence and the reasoning. A report should not become more certain simply because its inconvenient observations have been removed from view.

This does not require treating every imaginable possibility as equally plausible. An investigation must choose alternatives that are relevant to the architecture, environment, and observation. Their selection can be justified by known mechanisms and by the consequences of being wrong. What matters is that the selected alternatives remain open to discriminating examination and that important untested possibilities are not silently excluded. A catalogue of exotic causes can be as unhelpful as premature certainty when it supplies no predictions and no means of decision. Criticism should direct the next experiment, not merely multiply expressions of doubt.

The methodological role of the historical name must itself remain bounded. My participation here supplies a perspective on testability, not a historical endorsement of present receiver specifications. The engineering predictions belong to the models and evidence identified in this volume. Where those predictions fail, one must examine both the proposed source explanation and the auxiliary assumptions concerning the instrument. A single adverse result can be consequential without uniquely identifying which assumption failed. The responsible response is to formulate further discriminating tests or narrow the claim, while recording why that change is warranted.

Copyright 2026, James M. Atkinson

Dr. Atkinson, the proposed three-way distinction between a qualifying detection, a valid negative observation, and an indeterminate interval is valuable precisely because it can be criticised. Each category should have conditions that a reviewer can inspect. Indeterminate must not become a refuge used only when the result is inconvenient. Nor should it be suppressed because a client expects a decisive answer. The same classification rule should govern an interval that appears favourable and an interval that appears adverse to the investigator's preferred account. Its proper use identifies a missing observation or unsupported condition and explains what would be needed to resolve it. That account can guide action while refusing to invent evidence. [A1]

There is also a difference between an explanation that fits the retained record and one that survived a test designed to discriminate it. Fitting can be useful for proposing a mechanism. It does not independently establish that mechanism when several candidates can fit the same observations or when the adjustment itself has absorbed the distinguishing discrepancy. The report should separate exploratory modelling from the subsequent challenge. A successful challenge supports the limited proposition it was designed to test; it does not confer a general immunity from further criticism.

My proposed reporting discipline would therefore name the conclusion, its supporting observations, the alternatives actually examined, the predictions used to distinguish them, and the unresolved conditions. Agreement among the participants should not be manufactured where the observations leave a material question open. A properly bounded disagreement can expose the most valuable next test. The achievement is

Copyright 2026, James M. Atkinson

not the appearance of unanimous assurance, but a record in which another competent examiner can locate the premise they dispute and identify an observation capable of changing the result. Dr Wiener, may I invite your question concerning the feedback between the observer, the adaptive instrument, and the evidence subsequently offered for its own reliability?

Norbert Wiener

Peer question 7 to Karl R. Popper

Sir Karl, thank you. Our observer is not always outside a fixed experiment. The receiver can change its gain, tuning, or threshold in response to the very activity being investigated, and the operator can alter the search after seeing its first results. Dr. Atkinson has asked for a record that preserves these changes, but recording them does not by itself remove their effect on the evidence selected for review. Suppose the instrument preferentially retains intervals that its own detector finds interesting and discards the remainder. A later examiner then sees a collection shaped by that detector's responses. How can your requirement for a genuinely discriminating test accommodate this feedback without pretending that adaptation is inherently improper? In particular, what evidence would distinguish successful discovery from a selected archive that exaggerates persistence, suppresses contrary observations, or leaves negative coverage unestablished because the unretained intervals were never independently examined under an adequate procedure?

Copyright 2026, James M. Atkinson

Sir Karl Raimund Popper

Answer to Norbert Wiener

Dr Wiener, the feedback must become part of the account of how the observations were selected. A discovery procedure can legitimately concentrate attention on promising intervals. What it cannot do is present the selected archive as though it were an unselected observation of the entire period. The claim should identify the selection rule and the information retained about intervals that were not stored. A collection of triggered events may support investigation of those events while leaving their prevalence, the completeness of the search, or the conditions of non-detection unresolved. [V1, V16, A1]

Dr. Atkinson, the proposed distinction is between discovery and the test of a subsequent claim. Discoveries may be opportunistic. A hypothesis suggested by them can then be examined through a separately specified acquisition or a genuinely held-out record appropriate to the proposition. If the instrument continues to adapt during that test, its adaptation must be part of the defined procedure and the validation must address the relevant operating conditions. Calling a sequence adaptive neither excuses selection bias nor makes the sequence scientifically useless.

Your archive should therefore preserve coverage information and material state transitions in addition to selected events. It should show what the detector could retain, what it actually retained, and where validity was unknown. Where the search was redirected by a preliminary result, the chronology should make that redirection

Copyright 2026, James M. Atkinson

visible. These records allow a reviewer to distinguish evidence about an observed event from evidence about the completeness of observation. They do not manufacture the missing intervals, but they prevent the absence of those intervals from masquerading as evidence of absence.

I would finally ask that the proposed discovery mechanism itself be challenged with cases capable of exposing its omissions, not only with examples it already favours. That is a practical response to feedback: study the coupled observer and instrument as the procedure actually used, including the choices that determine which observations can subsequently be inspected. Professor Atkinson, I return the floor to you for the closing synthesis, with the reservation that our agreed record architecture supports bounded conclusions rather than a universal certificate of source identity.

Jerzy Neyman, Cross-Peer Question to Edward Weston: Mr Weston, your insistence upon a declared reference plane is persuasive for a stable measurement, but I want to know whether the practitioner can test the claim when the specimen and receiver environment are capable of changing during the test. Suppose a weak spectral component is observed at the receiver connector with a calibrated reference source nearby. The operator repeats the experiment after exchanging a cable and finds agreement within a small numerical tolerance. That agreement might arise because both configurations share the same unrecognised source of error, because the component changed at the same time as the chain, or because the reported tolerance was selected after the results became known. How would you design the comparison so that agreement and disagreement

Copyright 2026, James M. Atkinson

have measurable significance? Please identify the objects requiring independent observation, the assumptions carried by the correction from one connector to another, and the means of reporting an apparently successful comparison whose uncertainty budget still excludes an important systematic mechanism.

Edward Weston, Cross-Peer Answer to Jerzy Neyman: Professor Neyman, an observer who has only the final corrected values has no adequate basis for declaring that two physical experiments were comparable. The first act must be to define the measurand, including the receiving plane, frequency and time interval, bandwidth, detector, loading and operating state. For each arrangement we should retain both the indication at the actual measurement connector and the independently characterised transfer of the intervening path. The calibrated reference source should be characterised before it is trusted as a witness. Its level, spectral purity, connection geometry and own temporal stability may all become relevant. Agreement between two numbers corrected using the same erroneous gain table would not establish physical correctness, and that possibility should be incorporated into the experimental design. I would use a bounded sequence that separates changes in the environment from changes in the receiver path. First, observe a stable reference and the candidate simultaneously with the original path. Second, change the cable or attenuator under a plan fixed before seeing the outcome, retaining a controlled input and the actual switch time. Third, return to the original configuration and repeat the reference observation. Finally, where feasible, substitute a comparator system that changes the relevant error mechanism rather than merely carrying the same software correction into another

Copyright 2026, James M. Atkinson

enclosure. The procedure should include tests under conditions in which the expected candidate response is known to fail, for otherwise a failure-detection method may never have been challenged. Uncertainty is not a decoration added after the numbers agree. A correction for an identified passive loss has a sign, frequency dependence, loading condition and calibration uncertainty. An amplifier's gain depends upon level, state and possibly temperature. When the same calibration source or algorithm enters both estimates, covariance can be material. We should not simply divide its uncertainty by the square root of the number of repeated traces. Nor can an interval containing an unknown state transition be made valid by widening the final error bar. The state must be reconstructed or its corresponding result reported as conditional or unavailable. A successful comparison should therefore be reported narrowly: under the stated conditions, the two estimates were consistent to an identified criterion that accounted for the measured variability and specified systematic influences. If a consequential coupling path or state was not tested, name it plainly. The experiment can still be valuable because it narrows the set of plausible explanations and tells the next investigator what measurement would have the greatest power to discriminate them. I would not ask an engineering result to prove more than its chain of observation permits.

Edward Weston, Cross-Peer Question to Harry Nyquist: Professor Nyquist, your analysis of sampled representation is indispensable, yet instruments sometimes report an extraordinarily stable apparent phase in spite of short interruptions to their acquisition clocks or memory transfers. A recording may contain an exact number of samples and a plausible centre-frequency label while a hidden automatic gain change, a sample-index discontinuity or

Copyright 2026, James M. Atkinson

an interpolating firmware stage has altered the intended measurement. An expert might nevertheless calculate an FFT, compare nominal noise floors and report that no transient occurred. Which observations would you require before treating the samples as a continuous physical-time record? Can a band-limited reconstruction be invoked to fill an interval whose original samples were never acquired? Explain, also, how you would compare two channels disciplined by a common nominal oscillator when the physical distribution delays and reference switching may differ, and how the limits should appear in the technical evidence. I seek a practical acceptance test, not merely a mathematically attractive reconstruction of missing information.

Harry Nyquist, Cross-Peer Answer to Edward Weston: Mr Weston, the mathematical ability to reconstruct a band-limited waveform from a suitable sample sequence is not an assurance that an instrument supplied such a sequence. A sampling theorem requires hypotheses about the input, its admitted band, sampling times and the information retained. It cannot create missing samples merely because software knows the nominal conversion rate. The instrument record must therefore distinguish physical acquisition, buffering, processing and display. A contiguous file offset is not by itself a contiguous sample history. I would require an unambiguous hardware index, a known relationship between the index and the sample aperture under the actual clock state, and a record of missing, duplicated, reordered or deliberately discarded samples. When the instrument changes acquisition rate or reference source, the affected samples and settling intervals should be separately identified. For a complex SDR channel we must also specify its frequency convention. A negative baseband frequency,

Copyright 2026, James M. Atkinson

after frequency conversion and possible inversion, need not denote a different physical emitter. Likewise, a phase difference between channels is meaningful only after propagation and channel-transfer contributions have been declared. A shared reference can reduce some relative-frequency errors but can also introduce common phase steps which two channels repeat. Cable delay, distribution-amplifier noise, clock multiplication and the analogue frequency-conversion paths can still differ. An experiment comparing two channels should inject a controlled signal through independently characterised paths while capturing the phase relationship before and after deliberate switching, reference loss and reacquisition. Repeatability of a displayed phase under the same shared failure mechanism is not independent evidence of continuity. Interpolation across a gap may be an appropriate derivative product when the signal model and purpose justify it. It is not an acquired observation. An analyst might fit a sinusoid through two retained windows and obtain a continuous extension, but another waveform agreeing with both windows could have occupied the gap. Quantify the model dependence, retain the gap markers and label the reconstructed interval. A model that forces phase continuity may be extremely helpful for recovering an authorised communication from a clean channel, yet it cannot then be used as an independent test that phase continuity was physical. Finally, separate the spectral statistic from the event question. An FFT peak or reduced noise floor can be statistically well behaved while failing to observe a brief pulse or a reference transition. Observation opportunity depends upon when the receiver actually sampled the relevant frequencies and which samples survived filtering, gating and buffering. The evidential statement should identify actual acquired intervals,

Copyright 2026, James M. Atkinson

valid clock states and the signal classes tested. Without those conditions, numerical precision is not an answer to the question whether the relevant event could have been seen.

Harry Nyquist, Cross-Peer Question to Claude Elwood Shannon: Dr Shannon, an investigator often retains an attractive spectrogram, a list of detections and perhaps a demodulated audio excerpt but discards the original complex samples after processing. Those derived products may be compact and useful, especially in a survey with limited storage; nevertheless, the decision of what to keep may have been made by a threshold detector whose own errors are unknown. A later reviewer asks whether a weak transient, a phase-reversed signal, or a different waveform of the same power might have been present during a rejected interval. Which claims remain possible from the derived products, and which become formally unidentifiable? How would you distinguish a defensible compression or event-retention policy from a process that silently turns discarded data into an assertion of absence? Please address both reproducibility and lawful minimisation, because indiscriminate retention is not automatically authorised merely because complete samples would be analytically convenient. I particularly ask which original observations must remain distinguishable from software-generated hypotheses after extraction.

Claude Elwood Shannon, Cross-Peer Answer to Harry Nyquist: Professor Nyquist, we should start from the map between the original observed waveform and the retained representation. A magnitude-only spectrum can be well suited to estimating energy under a specified window, bandwidth and calibration. It cannot in general recover the original complex phase, sample chronology or event timing. A detected-event list can be suitable for

Copyright 2026, James M. Atkinson

counting events that exceed a particular validated criterion. It cannot prove that no other event occurred unless the detector's operating characteristics, observation opportunity and retained evidence justify such a claim. A demodulated fragment may retain intelligible content but discard the carrier, phase-noise and modulation characteristics needed for a different forensic question. Each output is thus useful, but only in relation to the questions it can still answer. An event-driven recorder should preserve a coverage ledger as carefully as it preserves the selected events. The ledger identifies bands and valid time intervals actually examined, detector thresholds, effective bandwidths, gain and overload states, clock quality, and known losses of acquisition or processing. When the detector fires, the retained complex samples should include the preceding history needed to evaluate the trigger and the following interval needed to understand the event. Multiple simultaneously observed subbands may require an explicit association across channels, preserving hardware indices and phase-calibration states rather than silently stitching them into a synthetic waveform. If no event is retained from a valid interval, the resulting statement is that none met the particular criterion in the observed domain. It is not universal proof of electromagnetic silence. The decision to discard raw data also has a lawful boundary. One cannot justify retaining all incidental communications merely because a future hypothesis might benefit from them. The proper design follows the authorised technical question and uses the least intrusive retention that leaves the necessary evidence reviewable. In some cases calibrated statistical summaries with controlled validation will be sufficient. In others the question requires original I/Q samples and an event-dependent protected recording. A policy

Copyright 2026, James M. Atkinson

should define those cases in advance, distinguish metadata about measurement validity from communication content and disclose when privacy constraints limit later reconstruction. A cryptographic digest of a retained product establishes byte correspondence under its custody chain, not the truth of the conclusions selected by the processing algorithm. Nor does a later successful reproduction of the same software output prove that the upstream detector was sensitive to the unknown event of interest. A proper independent challenge uses held-out physical test emissions, including weak and nonconforming cases, and compares what the recording system retains against an independently instrumented reference. Report misses as misses, not as noise-only successes. By preserving what the system decided, how it decided, and what it never observed, an investigator can give a compressed record a defensible evidential meaning without pretending that lost information remains available.

Claude Elwood Shannon, Cross-Peer Question to Jerzy Neyman: Professor Neyman, your discussion of specified error probabilities is vital when a receiver searches many spectral cells. Yet a technical survey seldom tests only one fixed frequency and one noise hypothesis. It may search millions of overlapping FFT bins across changing gain states, then choose a handful of visually striking candidates and ask an examiner to explain them. A report sometimes quotes a low single-bin false-alarm probability as though that were the probability of an erroneous conclusion after the entire adaptive search. How should the practitioner formulate a valid test when the search region, threshold and follow-up measurements can change in response to earlier observations? What must be retained to distinguish discovery from independent confirmation? I also ask how an unresolved receiver artefact

Copyright 2026, James M. Atkinson

should affect the interpretation of a statistically significant peak, and whether a negative observation in unexamined frequency-time cells can ever be included in the stated error probability. Would an explicit held-out challenge set change that assessment?

Jerzy Neyman, Cross-Peer Answer to Claude Elwood Shannon: Dr Shannon, the first safeguard is to define the experiment whose error probability is being reported. The probability of a threshold crossing in one prespecified noise-only cell is not the probability that some cell exceeds the same threshold after an extensive search. Nor is a confidence interval calculated for a candidate selected because it looked extreme automatically valid as an unconditional interval for that selected candidate. Dependence among adjacent FFT bins, overlapping windows and repeated acquisitions must be addressed by the test design or a validated approximation. The entire search procedure is the relevant statistical object: it includes candidate generation, adaptive processing, rejection criteria, exclusions and any selection of favourable intervals. I would separate exploration from confirmation. Exploration may search broadly and adaptively to discover a component worth investigating. Its function is to generate hypotheses. Confirmation then uses a declared measurement protocol chosen independently of the confirming data, with a defined reference plane, detection statistic, permitted operating states and controlled challenge conditions. The confirming record must be capable of observing the proposed event class; otherwise a nondetection is not a valid refutation. If independent confirmation is impossible, report the exploratory finding as exploratory and qualify its error probability. Do not transfer a probability calculated for one narrow test into a conclusion about the entire

Copyright 2026, James M. Atkinson

investigation. Instrumental artefacts create a further distinction. A statistically extreme spectral line may genuinely depart from a model of random receiver noise while still originate in a local oscillator, clipping, intermodulation or clock distribution. Statistical significance rejects a specified statistical model, not every alternative physical explanation. A useful test therefore changes one or more causal conditions: input termination, known attenuation, preselection, clock source, equipment location or a separately controlled receiver architecture. Under each change, make the predicted response explicit for the competing hypotheses. A comparison that changes detector sensitivity at the same time as the proposed causal variable must account for that change rather than attribute every difference to source identity. Unobserved cells cannot be treated as negative observations unless an independent bound or probability model justifies their inclusion. A receiver's wide tuning range does not imply that all those frequencies were examined at the relevant times, and a clean average trace does not establish response to a short transient. Record actual frequency-time coverage, the selected confidence convention and the relation between the expected event and the observation schedule. If false alarms or missed events cannot be estimated with acceptable precision, state that limitation. Useful scientific evidence remains possible, but the claim must not be presented with an invented numerical certainty. The resulting report should state an observed component, a measurement procedure, a justified statistical comparison, and the physical alternatives that survived controlled challenges. It should identify which confirmation data were independent and which shared the discovery process or calibration. Such a report will be less dramatic than a declaration of

Copyright 2026, James M. Atkinson

universal certainty, but it will be much more resistant to a legitimate technical objection.

Dr. James M. Atkinson

Closing synthesis

Mr Weston, Dr Nyquist, Dr Shannon, Professor Neyman, Sir Karl, and our seven questioning colleagues, thank you. The discussion has identified several different conditions that must not be compressed into a single assertion that the receiver is trustworthy. Mr Weston distinguished the physical comparison from its displayed indication and the applicability of a reference from the prestige of its calibration history. Dr Nyquist then showed why a faithfully retained sequence can still leave the admitted input ambiguous. Dr Shannon distinguished the integrity and size of a representation from its ability to answer a particular later question. Professor Neyman located performance claims within a defined experiment and trial population. Sir Karl required the resulting account to remain open to observations that would materially change its interpretation.

The peer exchanges sharpened those positions rather than merely endorsing them. Professor Bridgman required the measured quantity to survive a change of method without relying on an ambiguous label. Dr Shewhart challenged the inference from satisfactory endpoint checks to uninterrupted validity. Dr Bode identified the unresolved analogue state that can precede correctly sampled data. Mr Hartley refused a single league table of bandwidth and word length, while Professor Gabor distinguished the event from the analysis interval and display that represent it. Professor Pearson separated a fixed adaptive procedure from a fixed numerical

Copyright 2026, James M. Atkinson

threshold. Dr Wiener exposed the selection introduced by a search that changes in response to its own discoveries.

Our resulting doctrine is specific. A significant receiver finding should retain a traceable relation among its claimed quantity, physical reference plane, acquisition state, source interval, processing transformation, and decision rule. A comparison should identify what changed and what remained sufficiently comparable. A performance claim should identify the tested population and its uncertainty. A negative observation should identify valid exposure rather than borrow assurance from scheduled time alone. These requirements reinforce the volume's existing distinction between detection, classification, attribution, and content recovery; they do not collapse those distinct achievements into one result. [V1, V10, V16, A1]

Several questions remain deliberately unresolved. No universal recovery interval has been prescribed. No single retention format has been declared sufficient for every future question. No generic statistical percentage has been made applicable to every signal or environment. These omissions are not gaps to be filled with confident numbers. They identify dependencies that the relevant later chapters and experiments must address. Where a practical decision must precede their resolution, the report should state the supported observation, the missing premise, and the consequence of that limitation for the proposed use.

The next primary question will examine how the intended measurement should determine the receiver architecture and the location of its reference planes. That discussion should begin from the distinctions established here, not repeat their introduction. For this question, our conclusion is that evidence formation is a controlled sequence of physical comparisons and

Copyright 2026, James M. Atkinson

stated inferences. Its quality lies in the reader's ability to test the connections between them. The visible trace remains important, but its persuasive appearance must never substitute for those connections.

Ten worked engineering applications | Question 001

Application 01. Thermal reference noise in a declared measurement bandwidth

In the illustrative 001.01 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. Take the equivalent noise bandwidth B = 4,500 Hz and calibrated noise figure NF = 2.70 dB at an assumed 290 K. The thermal-reference estimate is N = $-174 + 10 \log_{10}(B/1\ \text{Hz}) + NF$ = -134.77 dBm. The result is available-noise power in that specific bandwidth; impulsive interference at the antenna is not represented by the 290 K assumption. Restrict the finding to the directly observed response and its demonstrated uncertainty.

Application 02. Filter or cable rejection referred to a physical input

In the illustrative 001.02 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. For an admitted input P_i = -43 dBm and separately measured loss L = 25 dB, the linear prediction is $P_o = P_i - L$ = -68 dBm. In SI power this becomes 10^((-68 − 30)/10) = 1.58e-10 W. That equality presumes a consistent power reference plane and no alternate common-mode ingress; a different screen level should prompt a physical bypass test. Restrict the finding to the directly observed response and its demonstrated uncertainty.

Application 03. Difference between two instruments relative to stated uncertainty

In the illustrative 001.03 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. The paired instrument contrast is Δ = 1.110 dB. Set independent standard

Copyright 2026, James M. Atkinson

uncertainties u_1 = 0.340 dB and u_2 = 0.470 dB. Then $u\Delta = \sqrt{(u_1^2 + u_2^2)}$ = 0.580 dB, giving the dimensionless ratio $\Delta/u\Delta$ = 1.914. This ratio is not automatically a significance test: correlated calibration errors and non-normal uncertainty require separate treatment. Restrict the finding to the directly observed response and its demonstrated uncertainty.

Application 04. Family-wise probability when many candidates are searched

In the illustrative 001.04 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. If each of M = 161 independent pre-specified search opportunities has false-alarm probability α = 0.0008, the probability of one or more false positives is 1 − (1 − α)^M = 0.12090, or 12.09%. Independence is a working premise only; neighbouring FFT bins and overlapping time windows commonly violate it. A post-selected search also changes the test family. Restrict the finding to the directly observed response and its demonstrated uncertainty.

Application 05. Preserved sample continuity across an acquisition interval

In the illustrative 001.05 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. A converter expected to retain f_s = 1.30 million samples/s for T = 1.15 s should supply f_sT = 1,495,000 complex sample instants. If 82 sequence positions are missing, the retained count is 1,494,918 and loss fraction is 0.00548%. A low fractional loss cannot exclude a highly relevant short burst coinciding with the gap. Position and timing of each missing block

Copyright 2026, James M. Atkinson

must therefore be preserved. Restrict the finding to the directly observed response and its demonstrated uncertainty.

Application 06. Observed exposure fraction of a channel scanner

In the illustrative 001.06 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. Let the channel be observed on n = 171 valid visits, each lasting d = 6 ms, with revisit spacing R = 0.55 s. Valid exposure is nd/1000 = 1.026 s across the nominal interval nR = 94.05 s. The observed fraction of elapsed time is therefore 1.09%, which is receiver coverage, not occupancy of the unvisited intervals. An occupancy percentage based only upon positive visits requires a separate sampling design. Restrict the finding to the directly observed response and its demonstrated uncertainty.

Application 07. Combined and expanded measurement uncertainty

In the illustrative 001.07 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. For independent standard-uncertainty contributions 0.52, 0.48 and 0.46 in a common unit, the root-sum-of-squares combination is $u_c = \sqrt{(0.52^2 + 0.48^2 + 0.46^2)} = 0.844$ units. Using an illustrative coverage factor k = 2 gives expanded uncertainty $U = 2u_c = 1.688$ units. Restrict the finding to the directly observed response and its demonstrated uncertainty.

Application 08. Stored-sample volume and the limits of retrospective analysis

In the illustrative 001.08 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. With complex sample rate f_s = 3 MS/s, duration T = 36 s, and 16-bit in-phase plus 16-bit quadrature integers, the raw payload is $f_sT \times 4$ bytes =

Copyright 2026, James M. Atkinson

432,000,000 bytes, or 0.432 GB (decimal). The calculation excludes timestamps, metadata, framing and file-system overhead. Maintaining a wideband buffer of this capacity does not establish that upstream analogue clipping was absent. Restrict the finding to the directly observed response and its demonstrated uncertainty.

Application 09. Accumulated sample-clock time error

In the illustrative 001.09 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. A free-running sample clock with fractional rate error $\varepsilon = 0.950$ ppm over $T = 438$ s accumulates nominal offset $\Delta t = \varepsilon \times 10^{-6} T = 0.4161$ ms. This model applies to an approximately constant mean rate error, not oscillator phase noise or dropped acquisition blocks. Comparing two differently disciplined clocks requires separate treatment of correlated reference errors and the timestamp tagging point. Restrict the finding to the directly observed response and its demonstrated uncertainty.

Application 10. Cascade gain and observed headroom

In the illustrative 001.10 test, a calibrated receiver indication is compared against a challenged antenna-side reference plane. A first amplifier contributes $G_1 = 10$ dB, an intentional attenuation contributes $G_2 = -8$ dB, and a later stage contributes $G_3 = 16$ dB. The small-signal sum is 10 + (-8) + 16 = 18 dB. For $P_i = -69$ dBm, the ideal output is $P_o = -51$ dBm. An intermediate amplifier may saturate even when the overall result appears modest, so the level before every nonlinear stage must be examined. Restrict the finding to the directly observed response and its demonstrated uncertainty.

QUESTION 002

Copyright 2026, James M. Atkinson

How should the intended measurement determine the receiver architecture and its reference planes?

Source: V011_Roundtable_Q001-Q011_CP011_Integrated_Candidate(2).docx | Recovered substantive manuscript. Constructed educational dialogue.

Constructed educational dialogue. The speeches are newly authored, not historical quotations or a transcript. Numerical cases are hypothetical and do not certify an instrument.

Dr. James M. Atkinson

Opening question

Professor Bridgman, can you comment on how the intended measurement should determine the receiver architecture and the physical locations of its reference planes? Our previous discussion separated an observation from a warranted claim. This discussion must turn that distinction into an engineering choice. We are not selecting an instrument by its largest advertised bandwidth or its most imposing numerical display. We are deciding what relationship must survive between an external electrical quantity, the receiver's internal transformations, and the result retained for examination. A suitable architecture for discovering an intermittent component may differ from an architecture for measuring its phase, and neither purpose automatically establishes the ability to recover an earlier waveform.

Consider two hypothetical acquisition paths. The first offers broad instantaneous coverage and internal calibration. The second admits a narrower band but allows a reference stimulus to traverse more of the input chain. Both report calibrated amplitudes. Neither deserves preference until the quantity and required uncertainty are stated. We must determine which

Copyright 2026, James M. Atkinson

path demonstrates the comparison under the signals, states, and transitions encountered, without presuming that narrower coverage necessarily provides greater accuracy.

Our source framework treats a measurement model as a relationship involving the quantities required to obtain the intended result, and asks whether that model remains adequate within its declared range. The following receiver cases are the author's constructions, not examples reported by a standards committee. They will distinguish the meaning of the measured quantity, the physical transfer through a network, the information admitted by sampling, the stability of the operating regime, and the evidential support for accepting a correction. [M2-1]

Professor Bridgman will examine the choice of quantity. Dr Bode will consider transfer, memory, and inversion. Dr Nyquist will examine the boundary between an admitted analogue band and a recoverable sampled representation. Dr Shewhart will consider whether the calibrated regime persisted. Professor Neyman will distinguish an identified calibration relationship from an inadequately tested decision procedure. Seven colleagues will challenge particular propositions, not merely restate the need for caution. Each question will receive an immediate answer before the floor passes onward.

The reference-plane decision also fixes what a later disagreement means. Two laboratories may agree on their own connector measurements yet disagree after different external corrections. Before blaming either receiver, we must determine whether they measured the same quantity under comparable conditions and whether their correction chains have compatible uncertainty statements.

Copyright 2026, James M. Atkinson

I ask the panel to work ten illustrative cases through to their consequences. The numerical inputs are stipulated and must not be read as specifications of an actual receiver. Every calculation should identify what it proves within its model and what further observation would be needed before using it in an investigation. We must also keep architectural choice separate from institutional authority: an elegant equation does not establish that its inputs were measured, and a calibration certificate does not decide whether the intended conclusion is recoverable. Professor Bridgman, please begin with the decision that ought to precede the circuit diagram: what, precisely, are we asking the receiver to measure?

Copyright 2026, James M. Atkinson

Percy Williams Bridgman

The intended quantity governs the comparison

Dr. Atkinson, thank you. I would begin by refusing to let a familiar noun decide the experiment. Amplitude, strength, and sensitivity are useful words only after we have specified the operations and physical conditions that make them quantities in this case. A receiver can report a peak voltage, a root-mean-square voltage, or a time-averaged power without any arithmetic fault, yet those results answer different questions. The task is not to force every possible procedure into one vocabulary. It is to establish sufficient correspondence between the declared quantity and the chosen procedure that a second examiner can determine whether a changed method still addresses the same proposition.

In our first worked application, suppose a sinusoidal voltage is applied across an exactly stipulated resistance R of 50 ohms. Let V_{rms} denote root-mean-square voltage in volts and P the mean dissipated power in watts. The declared relation is P = V_{rms} squared divided by R. If the report's 10 millivolts is an RMS value, the mean power is 2 microwatts. If the same numerical voltage instead denotes the sinusoid's peak, its RMS value is smaller by the square root of two, and the mean power is 1 microwatt. The ambiguity has doubled the inferred power without changing a single digit in the reported voltage. We have stipulated a resistor and sinusoid; arbitrary impedances and waveforms require their corresponding models.

$$P = \frac{V_{rms}^2}{R}$$

$$P = \frac{(0.010)^2}{50} = 2 \times 10^{-6} W$$

Copyright 2026, James M. Atkinson

This first case supplies an architectural consequence. A detector intended to report the average power of a burst must preserve the interval and averaging convention required for that quantity. A peak-hold arrangement can still be valuable, but its held maximum is not the same result. If the aim changes from determining mean heating to protecting a stage against an instantaneous excursion, the appropriate retained statistic can change. That is a change in the question, not necessarily an inconsistency in the instrument. The examiner should make this distinction before comparing outputs that happen to carry the same unit or occupy neighbouring columns in a report.

The second worked application concerns the order of correction. Let x be the input voltage in millivolts, y the indicated output voltage in millivolts, g a dimensionless voltage gain, and b an output-referred additive offset in millivolts. Stipulate y = gx + b with g = 100, b = 20 millivolts, and y = 1,020 millivolts. Removing the output offset before division gives x = 10 millivolts. Dividing first and then subtracting the same numerical offset gives minus 9.8 millivolts, an entirely different result. The correct alternative after division would subtract b divided by g, namely 0.2 millivolts. Reference plane and order are therefore mathematical commitments, not decorative annotations.

$$x = \frac{y - b}{g} = \frac{1020 - 20}{100} = 10\,mV$$

A calibration input situated after the element producing b may not expose that offset. Similarly, a source injected after a cable does not characterise the cable merely because the resulting readout is expressed as input-referred voltage. The location at which the reference enters

Copyright 2026, James M. Atkinson

determines which transformations the comparison exercises. I would therefore draw the physical path and mark the reference entry, the claimed measurand plane, and each correction boundary. Where a quantity is referred backwards across an unmeasured element, the report should identify the assumption or independent evidence that permits that referral. A software label cannot move the physical injection point.

Dr. Atkinson, this does not imply that every result must be measured at the antenna terminals. A receiver-input result can be entirely defensible when that is the declared quantity. The defect occurs when the conclusion quietly migrates to a different boundary. A laboratory may need an internal check for maintenance and an external comparison for the assembled measurement chain. Their coexistence is sensible, provided the internal check is not described as though it traversed the external components. A practical architecture can provide both facilities and preserve their distinct purposes in the acquisition record.

I would also distinguish the intended quantity from a supposed account of all reality. A finite measurement may deliberately average over phase, omit content outside a specified band, or retain only an event count. Such choices are not errors when the intended inference requires no discarded information. They become errors when a later claim depends on a distinction the procedure was never designed to preserve. The governing question is whether the relevant alternatives remain distinguishable in the chosen representation. That question connects the physical comparison to the sampling and evidential arguments that our colleagues will develop.

My recommendation is consequently a declared comparison, not a universal preference for one receiver. State the waveform class, electrical

boundary, temporal interval, estimator, and required uncertainty; then examine which architecture can sustain them in the actual environment. Where two architectures answer different questions, preserve both answers with their respective meanings. Mr Weston, may I invite your challenge concerning the relation between this specification and the practical calibration of a physical instrument? A further test of operational equivalence is to substitute two precision terminations with independently measured reflection coefficients at the same connector. The indication may change despite an unchanged source because the delivered power depends upon impedance. Record the calibration-plane mismatch, the cable loss and the receiver state separately. If the supposed quantity is field strength at an aerial rather than power available at the receiver input, the uncertainty must also include antenna-factor calibration, the local electromagnetic environment and the extent to which the receiving structure perturbs that environment. Such comparisons specify what another laboratory can reproduce without claiming that a meter reading alone determines the original physical field.

Edward Weston

Peer question 1 to Percy Williams Bridgman

Professor Bridgman, thank you. Suppose the customer asks for field strength at a particular location, but the receiver is directly calibrated only for power at its input connector. An antenna factor and cable correction are available from earlier measurements. Your account seems to permit a chain of comparisons, yet it could also be read as demanding that every element be measured anew in the final arrangement. How should the examiner distinguish a legitimate transfer from an

Copyright 2026, James M. Atkinson

unsupported extension? Dr. Atkinson has asked for an architecture that can be used, not merely one that can be criticised. In particular, what record would permit the retained antenna and cable information to support the new result, and what change would defeat that permission? Please distinguish the identity of an earlier calibration from evidence that its assumptions still apply to the present connection and surroundings. How would you state the uncertainty when no direct final-plane comparison is possible?

Percy Williams Bridgman

Answer to Edward Weston

Mr Weston, a chain of comparisons is legitimate when each link concerns the quantity and conditions actually needed for the result. I would not require fresh calibration as a ritual. I would require a reason why the earlier characterisation remains applicable. That reason may include a defined configuration, a supported frequency range, a condition history, and uncertainty that includes the transfer from the earlier arrangement to the present one. A certificate identifies a comparison performed; an applicability argument explains why its result may now be used. Those are related but separate evidential tasks.

For the proposed field-strength result, the antenna relationship must refer to the intended field quantity, orientation, loading, and environment within the model employed. A documented cable loss can support a receiver-input correction without establishing the antenna's response in an arbitrary surrounding structure. We should not collapse these links because their corrections can be added

numerically. Where the environmental contribution cannot be bounded adequately, the receiver-input measurement may remain reportable even though the requested field-strength inference requires qualification. The narrower result is not a failed measurement; it is the result actually supported.

Dr. Atkinson, a useful transfer record would therefore connect each correction to its source, declared domain, relevant physical configuration, and present verification. If a connector is replaced, the issue is whether that change is significant for the required uncertainty, not whether replacements are forbidden. An intermediate check might demonstrate continuity of a relevant response, but its scope must match the possible change. An internal source that bypasses the replacement cannot alone settle its effect.

The proposed architecture should make these distinctions easy to test. Accessible reference planes, recorded component identities, and a means of comparing the assembled response can be more valuable than an additional nominal digit. The residual uncertainty may still be acceptable for the investigation, or it may require a narrower claim. Mr Hartley, may I invite your question about whether a common numerical format is sufficient to preserve the distinction between the quantities being reported?

A further constraint follows from the fitness of receiver architecture and its reference-plane definitions for the intended measurand. I would add the following qualification to my answer. An instrument specification does not by itself establish the result of a field experiment. A preselector may reject one interfering band while

leaving a different ingress path; a sample clock may be stable in the mean while its phase fluctuates; and a file may be authentic while the analogue interpretation remains contested. The expert should distinguish a certificate describing a manufacturer test condition from a verified statement about the present configuration. Record the intervention and its physical reference, the raw output where available and the particular source hypothesis which the intervention could actually exclude. In this particular question, the controlled observation is measurements made at an explicit antenna, connector, preselector, or digital sample boundary, whereas the material uncertainty concerns the unattested voltage and phase before unknown transfer functions. Consequently the adversarial comparison ought to include a stepped reference-source comparison at each declared reference plane and its failed as well as successful outcomes. I would not advise treating a change in the displayed indication as an authenticated physical attribution until its causal mechanism has been experimentally distinguished.

Ralph Vinton Lyon Hartley

Peer question 2 to Percy Williams Bridgman

Professor Bridgman, I should like to examine that last distinction through two records of the same event. One preserves calibrated complex samples; the other retains integrated power in a sequence of short intervals. Both may estimate the mean power requested today. Tomorrow an examiner asks whether a phase change preceded an amplitude change. The first representation may support that inquiry and the second may not. Must the architecture therefore retain the most

Copyright 2026, James M. Atkinson

detailed representation available whenever future questions are unknown? Such a requirement could make every limited recording appear defective. Alternatively, may we define a defensible sufficiency relative to an explicit family of questions, while acknowledging that it does not preserve every possible distinction? Please explain how this choice should be disclosed so that an efficient acquisition is not later mistaken for an unrestricted archive of the electromagnetic event. The distinction should remain visible even when the original examiner is unavailable to explain the choice.

Percy Williams Bridgman

Answer to Ralph V. L. Hartley

Mr Hartley, sufficiency must be stated relative to the questions, not promoted into a universal attribute of a file. A sequence of integrated powers can be appropriate for a specified occupancy or mean-power analysis while excluding a later phase inquiry. The record should say what operation produced each retained value, over which samples and interval, with what calibration. It should also identify the principal distinctions that the operation intentionally discards. That disclosure permits a later examiner to recognise a new question as new, rather than assume that its answer was latent in a representation designed for another purpose.

The decision to retain a richer representation can be sensible where the anticipated analysis genuinely requires it and collection is authorised. It should not be justified through an unlimited promise of future recoverability. Complex samples themselves remain conditioned by the admitted band, quantisation, timing, and
